ABSTRACT: We study the two-point function for fermionic operators in a class of strongly coupled systems using the gauge-gravity correspondence. The gravity description includes a gauge field and a dilaton which determines the gauge coupling and the potential energy. Extremal black brane solutions in this system typically have vanishing entropy. By analyzing a charged fermion in these extremal black brane backgrounds we calculate the two-point function of the corresponding boundary fermionic operator. We find that in some region of parameter space it is of Fermi liquid type. Outside this region no well-defined quasi-particles exist, with the excitations acquiring a non-vanishing width at zero frequency. At the transition, the two-point function can exhibit non-Fermi liquid behaviour.

Contents

1 Introduction

The Gauge/Gravity correspondence [1–3] provides us with a new tool to study strongly coupled field theories. It is worth exploring whether insights of relevance to condensed matter physics can be gained using this tool. One set of questions which have proved difficult to analyze using conventional techniques is the behaviour of fermions in strongly coupled systems in the presences of a chemical potential. There has been considerable activity exploring this issue on the the gravitational side recently and some interesting lessons have been learnt from such studies. This question is particularly interesting in view of considerable evidence now for non-Fermi liquid behaviour in condensed matter systems, e.g., in High T_c materials and in heavy fermion systems close to quantum phase transitions.

Extremal black branes, which are at non-zero chemical potential and typically at zero temperature, are of particular interest in the gravity description in exploring this question. Some of the early studies have focussed on analyzing the behavior of fermionic fields in extremal Reissner Nordstrom (eRN) Black brane backgrounds [4–9]. While these black branes have the virtue of being simple and explicit they suffer from an important unphysical feature, namely, their entropy does not vanish despite their vanishing temperature. Instead, the entropy of these extremal solutions scales with the appropriate power of the chemical potential and increases as the chemical potential increases. It is widely believed that this big violation of the third law of thermodynamics is an artifact of the large N limit, and in the absence of supersymmetry or say the infinite number of symmetries in 1+1 dim. CFT's, this degeneracy should be lifted once finite N corrections are included.[1] In this context it is also relevant to note that quite often in string constructions extremal RN black branes have been found to be unstable, for example due to the presence of light charged scalars, [11].

In this paper we will consider $3 + 1$ gravity systems with a holographic field theory dual which is $2 + 1$ dimensional. The reservations discussed above for extreme RN black branes make it worth looking for other gravity systems where the extremal black branes are different so that their entropy in particular vanishes at extremality. Such a class of systems was explored in [12–14]. The key new ingredient was to include a dilaton which allows the gauge coupling of the Maxwell field to vary. It was found that as a result the black branes have zero entropy at extremality.[2] The dilatonic systems were further generalized by [15], see also, [16, 17], with both the gauge coupling and the potential energy now depending on the dilaton. Extremal black branes were often found to posses zero entropy in such systems as well.

These dilatonic systems, in particular their extremal black brane solution, are therefore a promising starting point for exploring questions related to the behaviour of fermionic fields. The behaviour of a bulk fermion in an extremal black brane solution of the type studied in [13, 14], was analyzed in [18, 19]. It was found that the two-point function of the corresponding fermionic operator in the boundary theory was qualitatively quite different from the non-Fermi liquid behaviour found in the eRN case and much more akin

---

[1]For some discussion of related issues in extremal black holes see [10].

[2]More precisely to ensure that higher derivative corrections are small one should introduce a small temperature. One then finds that the entropy density vanishes as a positive power of the temperature.

to a Fermi-liquid. The two-point function showed that there is a sharp Fermi surface in the system with well-defined quasi-particles excitations which have a linear, i.e., relativistic, dispersion relation at small frequency, and a width which has an essential singularity at vanishing frequency and which is therefore very narrow at small frequency.[3]

In this paper we will analyze the behaviour of a charged bulk fermion for the more general class of extremal dilaton systems studied in [15] and use it to calculate the two-point function of the corresponding fermionic operator in the boundary. We find that there is a wide range of behaviours that the fermion two-point function exhibits. One parameter in particular determines this behaviour, it is denoted by $\beta + \gamma$ below (for a definition of β, γ in terms of the parameters appearing in the Lagrangian eq. (2.4), see eq. (2.22), (2.23)). For $\beta + \gamma > 1$ one gets Fermi-liquid behaviour. At $\beta + \gamma = 1$ there is a transition. For $\beta + \gamma < 1$ there are no well-defined quasi-particle excitations since they acquire a big width which is non-vanishing as $\omega \to 0$.[4] The behaviour at the transition, when $\beta + \gamma = 1$, is also quite interesting. The geometries which correspond to this case include both extreme RN type solutions and other backgrounds where the entropy vanishes. These additional backgrounds, we find, also give rise to non-Fermi liquid behaviour of a type very similar to that seen in the extreme RN case first.

From the field theory point of view, the systems we analyze can be thought of as essentially free fermions coupled to a fermionic operator of a strongly interacting sector [18]. The near-horizon gravity solution provides a dual description of the strongly coupled sector. By varying the parameters β, γ we explore different kinds of strongly coupled sectors and the resulting change in the behaviour of the fermionic two-point function. Our central result is that the class of strongly coupled sectors which are described by our gravity backgrounds can give rise to the different types of behaviour mentioned above and to transitions among these kinds of behaviours. For example, at the risk of belaboring this point, our results show that Non-Fermi liquid behaviour of the type found first in [4] - [9] is more common and can occur without the large entropy of the eRN case. It also shows that transitions can occur across which well-defined quasi-particle excitations acquire a big width and cease to exist.

On general grounds we expect to be able to model only strongly coupled systems in the large N limit using a classical gravity description. This is a central limitation of our analysis. As a result the fermions we are studying are only a small subsector of a much bigger system with many degrees of freedom. It turns out that while the fermionic two-point function undergoes dramatic changes as the parameter $\beta + \gamma$ is varied, as was mentioned above, the geometry and other background fields change smoothly, signalling that most of the degrees of freedom of the large N "heat bath" in fact do not change their behaviour is a significant way. As a result, one finds that the thermodynamics and transport properties

---

[3]For a Fermi liquid the width is $O(\omega^2)$, which is much broader. It could easily be that additional interactions, e.g., of 4-Fermi type, which are suppressed in the large N limit, when incorporated can broaden out this width to the ω^2 behaviour of Fermi liquid theory. Keeping this in mind we will refer to such behaviour as being of Fermi-liquid type below. It is also worth mentioning that there are many additional gapless excitations in the system which contribute to the specific heat and the conductivity. For this reason such a phase is described as a fractionalised Fermi-Liquid (FL*) phase rather than a Fermi Liquid phase in [20–22].

[4]For a more precise description see section 3.5 and also section 4.

like electrical conductivity also do not change significantly; in particular the qualitatively big changes in the fermionic two-point function do not correspond to phase transitions. Once one goes beyond the large N limit one expects that the significant changes in the behaviour of the fermions, should they continue to occur, would also be accompanied by significant changes in thermodynamics and transport. A preliminary indication of this is provided by $1/N$ corrections to the electrical conductivity which is sensitive to the change in the Fermion two-point function and therefore to a change in its properties, [8, 9]. The results of this paper showing that behaviours other than of Fermi liquid type can arise in a fairly robust way may be taken as preliminary evidence that such behaviour is fairly generic in strongly coupled field theories and could occur beyond the large N limit as well.

Before proceeding it is worth commenting on some of the related literature. For a general discussion about phase transitions where the Fermi surface disappears and non-Fermi liquid behaviour can arise see [23]. A system with fermions living on probe branes with examples of Non-Fermi liquid phases and transitions due to the excitations getting gapped was found in [24, 25]. Some discussion of the Holographic description of a Fermi liquid can be found in [26]. Progress towards constructing an holographic description of the strange metal phase can be found in [27]. Recent progress in understanding the Holographic non-Fermi liquid phases often found in gravity systems in terms of fractionalised Fermi liquids and related ideas is contained in [20–22].

This paper is organized as follows. We begin by reviewing the dilaton system of interest and discuss the near-horizon geometry of extremal and near-extremal black branes in this system, along with some aspects of their thermodynamics and transport in section 2. The fermionic two-point function, for various ranges of parameters, is discussed in section 3. Section 4 contains a summary of main results and conclusions. Appendix A contains a discussion of additional extremal solutions, appendices B–D contain additional material useful for the fermion two-point function calculation and appendix E contains the calculation for the scalar two-point function. In appendix F we obtain a numerical solution interpolating between the near horizon geometry and AdS_4.

2 The dilaton gravity system

The system we consider consists of gravity, a U(1) gauge field, and a scalar, ϕ, which we call the dilaton, with action,

$$S = \int d^4x \sqrt{-g} \left\{ R - 2(\nabla \phi)^2 - f(\phi) F_{\mu\nu} F^{\mu\nu} - V(\phi) \right\}. \tag{2.1}$$

Note that for simplicity we have taken the kinetic energy term of the dilaton to be canonical. This restriction can be easily relaxed although we will not do so here.

The gauge coupling $g^2 \equiv (f(\phi))^{-1}$ and the potential $V(\phi)$ are both a function of the dilaton.

We will be particularly interested in solutions where the dilaton has a run-away type of behaviour near the horizon of an extremal black brane. Such run-away behaviour can result in the entropy of the extremal brane vanishing [13]. Also, we will be mainly concerned with

the low-temperature or low frequency (compared to the chemical potential) response of the system. On general grounds one expects that this response will be determined by the near-horizon geometry. Thus for our purposes we will mainly be interested in the behaviour of $f(\phi)$ and $V(\phi)$ when the dilaton has evolved sufficiently far along the run-away direction. We will take this behaviour to be of exponential type,

$$f(\phi) = e^{2\alpha\phi}, \tag{2.2}$$

$$V(\phi) = V_0 e^{2\delta\phi}. \tag{2.3}$$

The parameters α, δ thus characterize the run-away behaviour which occurs for $\phi = \pm\infty$. These parameters will repeatedly enter the discussion below. Substituting in eq. (2.1) then gives the action,

$$S = \int d^4x \sqrt{-g} \left\{ R - 2(\nabla\phi)^2 - e^{2\alpha\phi} F_{\mu\nu} F^{\mu\nu} - V_0 e^{2\delta\phi} \right\} \tag{2.4}$$

It is worth noting before we proceed that the full dependence of $f(\phi), V(\phi)$ away from the run-away region can be very different from these exponential forms. In fact, to obtain a solution which is asymptotically AdS_4 space, the potential $V(\phi)$ will need to have an extremum at a negative value of the cosmological constant and the dilaton will have to asymptote to this extremum far away from the horizon. However, these features of $f(\phi), V(\phi)$, and the corresponding features of the geometry, will not be very significant for determining the low-energy behaviour which will arise essentially from the near-horizon region. In field theory terminology these features correspond to UV data which is irrelevant for IR physics. The action eq. (2.4) therefore determines only the IR physics of the field theory. In the analysis below we will also take V_0 appearing in eq. (2.3) to satisfy the condition,[5]

$$V_0 < 0. \tag{2.5}$$

In this paper we will be interested in electrically charge black branes. Using the expected symmetries of the solution (translations and rotation in the x, y directions and time independence), the metric can be chosen to be of the form,

$$ds^2 = -a(r)^2 dt^2 + \frac{dr^2}{a(r)^2} + b(r)^2(dx^2 + dy^2) \tag{2.6}$$

The horizon of the extremal black brane will be taken to lie at $r = 0$. The gauge field equation of motion gives,

$$F = \frac{Q_e}{f(\phi)b^2} dt \wedge dr. \tag{2.7}$$

The remaining equations of motion can be conveniently expressed in terms of an effective potential as [28]

$$V_{\text{eff}} = \frac{1}{b^2} \left(e^{-2\alpha\phi} Q_e^2 \right) + \frac{b^2 V_0}{2} e^{2\delta\phi}, \tag{2.8}$$

---

[5]Since a negative cosmological constant is easier to obtain in string/M theory this choice for the sign of V_0 might be also easier to obtain in a string/M construction.

and are given by,

$$(a^2 b^2)'' = -2V_0 e^{2\delta\phi} b^2 \tag{2.9}$$

$$\frac{b''}{b} = -\phi'^2 \tag{2.10}$$

$$(a^2 b^2 \phi')' = \frac{1}{2}\partial_\phi V_{\text{eff}} \tag{2.11}$$

$$a^2 b'^2 + \frac{1}{2}a^{2'}b^{2'} = a^2 b^2 \phi'^2 - V_{\text{eff}}. \tag{2.12}$$

2.1 The solutions

In this subsection we will construct the near-horizon geometry for a class of extremal black brane solutions to these equations. Consider an ansatz[6]

$$a = C_a r^\gamma \qquad b = r^\beta \qquad \phi = k \log r \tag{2.13}$$

Note that a multiplicative constant in b can be set to unity by rescaling x, y, and an additive constant in ϕ, while subdominant at small r can be absorbed into V_0 and Q. With this ansatz, eq. (2.10) gives,

$$k^2 = \beta(1 - \beta) \tag{2.14}$$

Eq. (2.9) gives,

$$C_a^2(1 + \beta + k\delta)(1 + 2\beta + 2k\delta) = -V_0 \tag{2.15}$$

$$\gamma - 1 = \delta k. \tag{2.16}$$

Finally, eq. (2.11), eq. (2.12) give, on using $\gamma = 1 + \delta k$ and eq. (2.14),

$$\left(C_a^2 k(1 + 2\beta + 2k\delta) - \frac{\delta}{2}V_0\right) r^{4\beta - 2k(\alpha - \delta)} = -\alpha Q_e^2 r^{-4\alpha k} \tag{2.17}$$

and,

$$\left(C_a^2 \beta(1 + 2\beta + 2k\delta) + \frac{1}{2}V_0\right) r^{4\beta - 2k(\alpha - \delta)} = -Q_e^2 r^{-4\alpha k} \tag{2.18}$$

These last two equations can be met if the power of r and the coefficients match on both sides of each equation. This gives,

$$4\beta = -2k(\alpha + \delta) \tag{2.19}$$

$$C_a^2 k(1 + 2\beta + 2k\delta) - \frac{\delta}{2}V_0 = -\alpha Q_e^2 \tag{2.20}$$

$$C_a^2 \beta(1 + 2\beta + 2k\delta) + \frac{1}{2}V_0 = -Q_e^2 \tag{2.21}$$

---

[6]Actually the only assumption in this ansatz is that b has a power law dependence on r. Given this fact, eq. (2.10) implies that $\phi \propto \log r$, and eq. (2.9) implies (except for some special cases) that $a(r)$ is also a power law.

Solving, eq. (2.14), eq. (2.15), eq. (2.16), eq. (2.19), eq. (2.20), eq. (2.21), gives

$$\beta = \frac{(\alpha + \delta)^2}{4 + (\alpha + \delta)^2} \qquad \gamma = 1 - \frac{2\delta(\alpha + \delta)}{4 + (\alpha + \delta)^2} \qquad k = -\frac{2(\alpha + \delta)}{4 + (\alpha + \delta)^2} \qquad (2.22)$$

$$C_a^2 = -V_0 \frac{\left(4 + (\alpha + \delta)^2\right)^2}{2\left(2 + \alpha(\alpha + \delta)\right)\left(4 + (3\alpha - \delta)(\alpha + \delta)\right)} \qquad Q_e^2 = -V_0 \frac{2 - \delta(\alpha + \delta)}{2\left(2 + \alpha(\alpha + \delta)\right)} \qquad (2.23)$$

The following three conditions must be satisfied for this solution to be valid:

$$Q_e^2 > 0 \;\Rightarrow\; \frac{2 - \delta(\alpha + \delta)}{2 + \alpha(\alpha + \delta)} > 0 \qquad (2.24)$$

$$C_a^2 > 0 \;\Rightarrow\; \left(2 + \alpha(\alpha + \delta)\right)\left(4 + (3\alpha - \delta)(\alpha + \delta)\right) > 0 \qquad (2.25)$$

$$\gamma > 0 \;\Rightarrow\; 1 - \frac{2\delta(\alpha + \delta)}{4 + (\alpha + \delta)^2} > 0 \qquad (2.26)$$

The last condition arises from the requirement that g_{tt} vanish at the horizon, which we have taken to lie at $r = 0$.

Now note that the constraint, $Q_e^2 > 0$, can be satisfied in general in two ways: both the numerator and the denominator are positive or both are negative. The latter possibility, however, it is easy to see, violates the condition $\gamma > 0$. Therefore the conditions above can be reexpressed as,

$$2 - \delta(\alpha + \delta) > 0 \qquad (2.27)$$

$$2 + \alpha(\alpha + \delta) > 0 \qquad (2.28)$$

$$4 + (3\alpha - \delta)(\alpha + \delta) > 0. \qquad (2.29)$$

Note that from eq. (2.22), (2.23) and eq. (2.27),

$$\gamma - \beta = \frac{4 - 2\delta(\alpha + \delta)}{4 + (\alpha + \delta)^2} > 0. \qquad (2.30)$$

The parameter $\beta + \gamma$ will play an important role in the subsequent discussion. From eq. (2.22), (2.23) it takes the value,

$$\beta + \gamma = 1 + \frac{(\alpha + \delta)(\alpha - \delta)}{4 + (\alpha + \delta)^2}. \qquad (2.31)$$

Note that $\beta + \gamma = 1$ when $\alpha = \pm\delta$. The case $\alpha + \delta = 0$ has $\gamma = 1, \beta = 0$ and therefore corresponds to an $AdS_2 \times R^2$ geometry which is also the near horizon geometry in the extreme RN case. The case $\alpha = \delta$ has $\beta > 0$ and therefore corresponds to an extremal brane with vanishing horizon area.

2.2 More on the solutions

Here we comment on some properties of the solutions in more detail.

The solution in eq. (2.22), (2.23) has only one parameter V_0, in particular the charge too gets fixed in it in terms of this parameter. In the full solution, including the asymptotic region near the boundary, the charge or the chemical potential would of course be an

additional parameter, however this parameter does not appear in the near-horizon solution. The solution above eq. (2.22), (2.23) is actually an exact solution to the equations of motion, but in a situation where the asymptotic boundary conditions are different, say AdS_4, it will only be approximately valid at small values of r. And the chemical potential will enter in the determination for when the near-horizon geometry stops being a good approximation.[7]

If V_0 and μ are the only two scales in the geometry one expects that the near horizon geometry is a good approximation for

$$r \ll \frac{\mu}{\sqrt{|V_0|}}. \tag{2.32}$$

Note that r is dimensionless, μ and $\sqrt{|V_0|}$ have units of Mass,[8] thus this formula is consistent with dimensional analysis.[9]

Let us make a few more comments. When $\alpha + \delta$ does not vanish, $\beta > 0$, and therefore the area of the horizon and thus the entropy vanishes. Second, the solution has a smooth limit when $\delta \to 0$, and reduces to the black brane found in [13, 29] in this limit. Third, the solution is somewhat analogous to Lifhsitz type solutions [30–33], however, in general the metric in the solution does not have any scaling symmetry. Exceptions arise when $\gamma = 1$, which requires either $\alpha + \delta = 0$, the eRN case mentioned above, or $\delta = 0$, the case studied in [13]. Finally, after a suitable coordinate transformation it is easy to see that the solution we have obtained above, eq. (2.22), (2.23) agrees with the solution discussed in [15] in section 8, eq. (8.1a)–(8.1d), with the non-extremality parameter m set to zero.[10]

We will examine the thermodynamics of the near extremal solution next and also comment on electrical conductivity.

Before proceeding let us note that there is another class of solution to the equation of motion, also consistent with the ansatz, eq. (2.13), which is valid in a region of the (α, δ) parameter space which is different from the one described above. This class of solutions is discussed in appendix A. A further study of this additional class of solutions is left for the future, the discussion which follows will mainly focus on the extremal black brane solutions discussed above.

2.3 Thermodynamics of the slightly non-extremal black brane

Next we turn to constructing slightly non-extremal black brane solutions (these would have temperature $T \ll |\mu|$, where μ is the chemical potential). The following observation

---

[7]More generally, there could be additional scales, e.g., if a relevant operator is turned on in the boundary CFT, besides the chemical potential, to obtain the full geometry. In such a situation our comments apply if these additional scales are also of order the chemical potential. In appendix F we will in fact construct examples of such solutions where the relevant operator is dual to the dilaton. For typical values of parameters considered there, the additional scale which corresponds to the coupling constant of this operator in the Lagrangian is of order μ.

[8]There is a hidden overall Newton constant G_N in the action (2.1).

[9]Another way to obtain (2.32) in the full solution viewpoint is to note that we need $r - r_h \ll r_h \sim \mu$ where r_h is horizon. By restoring the length scale of the system $\sim 1/\sqrt{|V_0|}$ and by coordinate transformation so that we set horizon to be $r = 0$, we obtain (2.32).

[10]For comparison purposes the parameters (α, δ) defined in this paper should be related to (γ, δ) in [15] as follows: $(\alpha, \delta) \to (\gamma, -\delta)$.

makes it easy to do so. Starting from the extremal solution, of the form, eq. (2.13), the equations of motion continue to hold if a term linear in r is added to $a^2 b^2$, while keeping b^2 and ϕ unchanged. This is straightforward to see for the first three equations of motion, eq. (2.9)–(2.11), and follows for eq. (2.12) after we note that it can be rewritten as,

$$\left(a^2 b^2 \frac{b'}{b} \right)' = -V_{\text{eff}}. \tag{2.33}$$

This observation allows us to construct a one parameter deformation of the extremal solutions, where

$$a^2 = C_a^2 r^{2\gamma} \left(1 - \left(\frac{r_h}{r} \right)^{2\beta+2\gamma-1} \right) \tag{2.34}$$

and b^2, ϕ take the form in eq. (2.13), with C_a, γ, β, k as given in eq. (2.22), eq. (2.23). The parameter r_h characterizes the deformation and corresponds to the location of the horizon. It is easy to see that the deformed solutions have a first order zero at the horizon and thus are non-extremal. For $r_h \ll 1$ these solutions are close to extremal.

Near the horizon,

$$a^2 \simeq C_a^2 (2\beta + 2\gamma - 1) r_h^{2\gamma-1} (r - r_h) \tag{2.35}$$

We note that for the solution in eq. (2.22), (2.23), the condition,

$$2\beta + 2\gamma - 1 > 0 \tag{2.36}$$

is indeed met, as would be needed for the region $r > r_h$ to correspond to the region outside of the horizon. It is simple to see that the temperature of the non-extremal black brane goes like,

$$T \sim r_h^{2\gamma-1} \tag{2.37}$$

and the entropy density scales like,

$$s \sim r_h^{2\beta} \sim T^{\frac{2\beta}{2\gamma-1}} \tag{2.38}$$

A physically acceptable extremal black brane, which corresponds to the ground state of a conventional field theory on the boundary, should have a positive specific heat when it is heated up. This leads to the additional condition for an acceptable solution,

$$2\gamma - 1 > 0 \tag{2.39}$$

When expressed in terms of α, δ this becomes,

$$4 + (\alpha - 3\delta)(\alpha + \delta) > 0 \tag{2.40}$$

This condition must be added to the three discused earlier, eq. (2.27)–(2.29). In figure 1 we show the region in the (α, δ) plane which meets all these four conditions.
Figure 1. Region allowed by the constraints.

2.4 Taming the singularity

In the discussion above we used classical Einstein gravity and worked in the two-derivative approximation. These approximations can break down at sufficiently small values of the radial coordinate r. For example, a curvature singularity could arise or the dilaton can diverge signalling such a breakdown. The essential point we want to make in this subsection is that turning on a temperature which is very small in the large N limit can often help control this breakdown. Our arguments are only suggestive at the moment, a definitive discussion would require an embedding of these dilaton systems in string theory which has not been done as yet.

The parameter

$$L = \frac{1}{\sqrt{|V_0|}} \qquad (2.41)$$

is an important length that characterizes the system. We will assume that L and the chemical potential μ are the only two scales in the system in the two derivative approximation. For example, if the geometry is asymptotically AdS_4 the radius of AdS_4 would be of order L. From eq. (2.22), (2.23) we see that L is also the only scale in the near-horizon solution. A measure of the number of degrees of freedom in the system is given by

$$N^2 = \frac{L^2}{l_{Pl}^2}. \qquad (2.42)$$

In the near-horizon geometry of the extremal solution the Ricci scalar, $\mathcal{R} \sim r^{2(\gamma-1)}/L^2$. The higher invariants $R_{\mu\nu}R^{\mu\nu}$ and $R_{\mu\nu\rho\sigma}R^{\mu\nu\rho\sigma}$ are also of the same order, i.e. $R_{\mu\nu}R^{\mu\nu} \sim (r^{2(\gamma-1)}/L^2)^2$ etc. We see that these invariants diverge at $r = 0$ for $\gamma < 1$.[11] At finite

---

[11]For $\gamma \geq 1$ tidal forces could still blow up, as happens in the Lifshitz solutions obtained when $\gamma = 1$, $\beta \neq 0$.

temperature the divergence is cutoff at the horizon located at $r = r_h$. We get

$$\mathcal{R} l_{pl}^2 \sim \frac{r_h^{2(\gamma-1)}}{N^2} \tag{2.43}$$

Expressing this in terms of the temperature

$$T \sim \frac{r_h^{2\gamma-1}}{L} \tag{2.44}$$

leads to

$$\mathcal{R} l_{pl}^2 \sim \frac{(TL)^{\frac{2\gamma-2}{2\gamma-1}}}{N^2} \tag{2.45}$$

We see that for $N^2 \gg 1$ the curvature can be made much smaller than the Planck scale by taking

$$\left(\frac{1}{N^2}\right)^{\frac{2\gamma-1}{2(1-\gamma)}} \ll TL \ll 1 \tag{2.46}$$

Thus the curvature can be made much smaller than the Planck scale, while keeping the temperature much smaller than $1/L$. In the large N limit, where $N \to \infty$, keeping L fixed, this condition is in fact met for any non-zero temperature.

However this analysis might be incomplete, since the 4 dim. Planck scale is a derived quantity in string theory and the criterion for breakdown of classical two-derivative gravity involves the curvature in units of the string scale, which is related to l_{Pl} via the values of moduli, and also involves the string coupling. It could be that requiring the curvature to be much smaller than the string scale imposes a stronger condition than eq. (2.46), or that a stronger condition arises by requiring that quantum effects remain small.[12]

For example, it could be that the dilaton enters in the relation between the string and Planck scale,[13] since the dilaton also varies with r this could change the condition for the validity of the two-derivative approximation. Similarly, the dilaton might also enter in the string coupling and the requirement that quantum corrections are small could impose significant restrictions. In fact this is likely to be the case. The gauge coupling in the action eq. (2.4) goes like $g^2 = e^{-2\alpha\phi}$. One would expect the theory to be weakly coupled only when $g^2 \ll 1$. The dilaton in the near horizon region is given by,

$$\phi = k \log(r/r_c) \tag{2.47}$$

where we have introduced a radial cut-off r_c on the r.h.s. . This leads to the condition,

$$e^{-2\alpha\phi} = \left(\frac{r_h}{r_c}\right)^{-2\alpha k} \ll 1 \tag{2.48}$$

When $\alpha k > 0$ this does not allow the temperature to become very small. The parameter r_c depends on the chemical potential, which determines how far out in r the geometry begins

---

[12]Another reason for thinking that there is more to this analysis is the condition eq. (2.46) involves L which does not directly have an interpretation in the boundary theory.

[13]The scalar we are calling the dilaton may not literally be the dilaton field of string theory whose expectation value determines the string coupling.

to depart from the near-horizon solution, and also can depend on the asymptotic value of ϕ. It could be that this condition can be met only if T is large compared to μ, this would require a temperature which is much too big, the resulting finite temperature black brane would not be described by the near-horizon metric we have found. Or it could be that if one starts with the asymptotic value of the dilaton being small enough this condition can be met while remaining within the scope of the solution we have found.

Clearly, this question about the validity of our solution, in the presence of a small temperature, will need to be revisited in a more complete string construction.

2.5 Conductivity

For completeness let us also comment on the electrical conductivity of this system. Our discussion follows [13] section 3 and [14] section 3 closely, we omit some details. Before proceeding let us note that the compution of the electrical conductivity in AdS/CFT is discussed in several other papers as well, e.g., [34–39]. The essential idea of our calculation, [35], is to cast the equation governing a perturbation of say the A_x component of the gauge field in the black brane background in the form of a Schrödinger problem,

$$-\frac{d^2\psi}{dz^2} + V(z)\psi = \omega^2\psi \tag{2.49}$$

where ω is the frequency. Starting at the boundary with an ingoing pulse one can calculate the reflection amplitude R from the potential $V(z)$. The conductivity is then given by

$$\sigma = \frac{1-R}{1+R}. \tag{2.50}$$

The dependence of the conductivity on ω, T, for small values of these parameters can be obtained, upto overall coefficients, by analyzing the behaviour of $V(z)$ in the near-horizon region. Thus our lack of knowledge of the full solution in the problem at hand will not be a limitation in extracting this information, although conceptually it is useful to assume that there is a screen eventually located in an asymptotically AdS region.

Some more details are as follows. The variable ψ is

$$\psi = f(\phi)A_x \tag{2.51}$$

and z is given in terms of the radial variable r used in the metric, eq. (2.6), by

$$\partial_z = a^2 \partial_r\,. \tag{2.52}$$

As discussed in appendix B, in the extremal near-horizon geometry,

$$V(z) = \frac{c}{z^2} \tag{2.53}$$

where the coefficient c, which is important for this calculation, takes the value,

$$c = 2\frac{(4+\alpha^2-\delta^2)(4+(\alpha-2\delta)(\alpha+\delta))}{(4+(\alpha-3\delta)(\alpha+\delta))^2}\,. \tag{2.54}$$

Defining

$$\nu = \sqrt{c + \frac{1}{4}},$$ (2.55)

it then follows from the analysis of section 3 in [13] for example that the optical conductivity, for $\omega \ll \mu$ at zero temperature, is given by,

$$Re(\sigma) \sim \omega^{2\nu-1} \sim \omega^{\frac{2(4+\alpha^2-\delta^2)}{4+(\alpha-3\delta)(\alpha+\delta)}}$$ (2.56)

Similarly, the DC conductivity, for $\omega \to 0$, for small temperature, $T/\mu \ll 1$, goes like,

$$Re(\sigma) \sim T^{2\nu-1} \sim T^{\frac{2(4+\alpha^2-\delta^2)}{4+(\alpha-3\delta)(\alpha+\delta)}}$$ (2.57)

as follows from the analysis in [14] section 3 for example. There is in addition a delta function at zero frequency in $Re(\sigma)$ which we have omitted above.

Note that using eq. (2.22), eq. (2.23), we can express the exponent

$$2\nu - 1 = \frac{2\gamma}{(2\gamma - 1)}$$ (2.58)

Since $2\gamma - 1 > 0$ from eq. (2.39), the r.h.s. is always positive thus the exponent in both the optical conductivity and DC conductivity are positive. This means the optical conductivity increases with increasing frequency and the DC conductivity increases with increasing temperature, with the system behaving in effect as one with a "soft gap".[14] As (α, δ) are varied $2\gamma - 1$ can become arbitrarily small (while remaining positive) and thus the exponent eq. (2.58) can become very large so that the increase with frequency or temperature is very gradual.

The result for the optical conductivity agrees with section 8 of [15]. The DC conductivity does not agree. The answer above corresponds to the DC conductivity as defined by the two-point current -current correlation function using the Kubo formula. The definition in [15], section 5, for the DC conductivity is different and related to the drag force on a massive charge.

3 Fermionic two point function

We will consider a free fermion in the bulk with mass m and charge q. Its action is

$$S_{\text{fermion}} = \int d^{3+1}x \sqrt{-g} i[\bar{\psi}\Gamma^M D_M \psi - m\bar{\psi}\psi]$$ (3.1)

We will mostly follow the spinor and related Dirac matrix notation of [5] and specifically comment on any differences below. In our notation then,

$$\bar{\psi} = \psi^\dagger \Gamma^{\bar{t}}, \quad D_M = \partial_M + \frac{1}{4}\omega_{abM}\Gamma^{ab} - iqA_M$$ (3.2)

---

[14]In a system with a conventional gap the conductivity would be exponentially sensitive to the temperature, going like, $Re(\sigma) \sim e^{\frac{-\Delta}{T}}$, instead of having the power-law behaviour we find.

where ω_{abM} is the spin connection and A_M is the vector potential. The gamma matrices,

$$\Gamma^r = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \Gamma^\mu = \begin{pmatrix} 0 & \gamma^\mu \\ \gamma^\mu & 0 \end{pmatrix} \tag{3.3}$$

with

$$\gamma^0 = i\sigma_2, \gamma^1 = \sigma_1, \gamma^2 = \sigma_3. \tag{3.4}$$

where $\sigma_i, i = 1, \cdots 3$ denote the Pauli matrices.

The spinor ψ has four components and we define $\psi_\pm$ to be the upper and lower two components respectively,

$$\psi = \begin{pmatrix} \psi_+ \\ \psi_- \end{pmatrix} \tag{3.5}$$

Using the translational symmetries we can take,

$$\psi_\pm = (-gg^{rr})^{-\frac{1}{4}} e^{-i\omega t + i k_i x^i} \phi_\pm \,. \tag{3.6}$$

Asymptotically,

$$\phi_+ = Ar^m + Br^{-m-1}, \quad \phi_- = Cr^{m-1} + Dr^{-m} \tag{3.7}$$

where A, B, C, D are 2 dim. column vectors. If we define $D = SA$ then The two-point function on the boundary for the dual operator is

$$G_R = -iS\gamma^0 \,. \tag{3.8}$$

We can simplify the calculations by using the rotational symmetry in x, y plane to choose $k = k_1$. Then writing

$$\phi_\pm = \begin{pmatrix} y_\pm \\ z_\pm \end{pmatrix} \,. \tag{3.9}$$

The equation of motion for ψ then breaks up into block 2×2 form coupling only (y_+, z_-) and (y_-, z_+) together respectively. The two-point function G_R has two non-vanishing components, G_{R11} and G_{R22}, these are related by, $G_{R11}(\omega, k_1) = G_{R22}(\omega, -k_1)$ and are not independent. In what follows we will set (y_-, z_+) to vanish, this is sufficient to extract G_{R22} and then also G_{R11}.

Also it will be convenient to make one change of variables and work with

$$z'_- = iz_- \tag{3.10}$$

instead of z_-.

The equations for (y_+, z'_-) take the form,

$$\sqrt{\frac{g_{ii}}{g_{rr}}} (\partial_r - m\sqrt{g_{rr}}) y_+ = -(k_1 - u)z'_- \tag{3.11}$$

$$\sqrt{\frac{g_{ii}}{g_{rr}}} (\partial_r + m\sqrt{g_{rr}}) z'_- = -(k_1 + u)y_+ \tag{3.12}$$

with

$$u = \sqrt{\frac{g_{ii}}{-g_{tt}}}(\omega + qA_t). \tag{3.13}$$

Asymptotically, towards the boundary,[15] it is easy to see that the solution take the form,

$$\begin{pmatrix} y_+ \\ z'_- \end{pmatrix} = C_1 \begin{pmatrix} 1 \\ -\frac{(\omega+\mu q+k_1)}{(2m-1)r} \end{pmatrix} r^m + C_2 \begin{pmatrix} \frac{-(\omega+\mu q-k_1)}{(2m+1)r} \\ 1 \end{pmatrix} r^{-m} \tag{3.14}$$

where μ is the asymptotic value of the gauge potential A_t. Comparing with eq. (3.7) and eq. (3.8) we find that

$$G_{R22} = -\frac{C_2}{C_1}. \tag{3.15}$$

In the near horizon region, eq. (2.22), (2.23) the fermion equations of motion, eq. (3.11), (3.12) take the form,

$$r^{\beta+\gamma}\left(\partial_r - \frac{m}{C_a r^\gamma}\right)y_+ = -\left(\frac{k_1}{C_a} - \frac{r^{\beta-\gamma}}{C_a^2}(\omega + qA_t)\right)z'_- \tag{3.16}$$

$$r^{\beta+\gamma}\left(\partial_r + \frac{m}{C_a r^\gamma}\right)z'_- = -\left(\frac{k_1}{C_a} + \frac{r^{\beta-\gamma}}{C_a^2}(\omega + qA_t)\right)y_+. \tag{3.17}$$

The explicit C_a dependence will vanish if we work with the rescaled variables, $m = \tilde{m}C_a, k_1 = \tilde{k}_1 C_a, (\omega + qA_t) \to C_a^2(\tilde{\omega} + \tilde{q}A_t)$. To avoid clutter we will refer to these rescaled variables $\tilde{m}, \tilde{k}_1, \tilde{\omega}, \tilde{q}$ as m, k_1, ω, q in the discussion below. Eq. (3.16) and (3.17) now take the form,

$$r^{\beta+\gamma}\left(\partial_r - \frac{m}{r^\gamma}\right)y_+ = -\left(k_1 - r^{\beta-\gamma}(\omega + qA_t)\right)z'_- \tag{3.18}$$

$$r^{\beta+\gamma}\left(\partial_r + \frac{m}{r^\gamma}\right)z'_- = -\left(k_1 + r^{\beta-\gamma}(\omega + qA_t)\right)y_+. \tag{3.19}$$

We will be interested in the retarded Green's function in the bulk, this is obtained by imposing in-going boundary conditions at the horizon. Very close to the horizon where ω term dominates, eq. (3.18), (3.19) become,

$$r^{\beta+\gamma} \, \partial_r \begin{pmatrix} y_+ \\ z'_- \end{pmatrix} = \omega r^{\beta-\gamma} \, i\sigma_2 \begin{pmatrix} y_+ \\ z'_- \end{pmatrix}. \tag{3.20}$$

The ingoing solution is obtained by taking

$$\begin{pmatrix} y_+ \\ z'_- \end{pmatrix} = \begin{pmatrix} 1 \\ -i \end{pmatrix} e^{-i\omega z} \tag{3.21}$$

where

$$z = \frac{1}{(1-2\gamma)r^{2\gamma-1}}. \tag{3.22}$$

---

[15]We are assuming here that asymptotically the spacetime approaches AdS_4, as happens for the examples considered in appendix F. While this is useful for extracting the field theory results, at low-frequency the essential features in these results really only depend on the near-horizon region.
Figure 2. Region with $\beta + \gamma > 1$ in blue; $\beta + \gamma < 1$ in green.

Note that the time dependence has been taken to be of form $e^{-i\omega t}$, eq. (3.6), and since $z \to -\infty$, at the horizon, where $r \to 0$, $e^{-i\omega(t+z)}$ is well behaved at the future horizon where $t \to \infty$.

We are interested in the small frequency behaviour of the boundary two-point function. At a Fermi surface, where $k_1 = k_F$, the boundary two-point function has a singularity, for $\omega \to 0$. We will be interested in asking whether such a surface can arise in this system and what is the nature of small frequency excitations near this surface. It will be convenient to divide our analysis into three parts, depending on the value the parameter $\beta + \gamma$ takes.

When $\beta + \gamma > 1$ we will see that the boundary fermionic two-point function is of Fermi liquid type. More correctly, as was discussed in the introduction the small frequency excitations have a linear dispersion relation, with a width which is narrower than ω^2. When $\beta + \gamma < 1$ we will find that the low-frequency excitations acquire a width which is non-vanishing even in the $\omega \to 0$ limit, and thus is very broad. The transition region, $\beta + \gamma = 1$ consists of two lines. One of them corresponds to extremal RN type geometries, which are well known to give Non-Fermi liquid behaviour [4–6]. The other corresponds to geometries which have vanishing entropy, here we find that the behaviour can be of both Fermi or non-Fermi liquid type with width $\Gamma \sim \omega^p$. The power $p > 0$ and can be bigger, equal to, or less than two, so that one can get both Fermi-liquid and non-Fermi liquid behaviour.

We now turn to discussing these three cases in turn. In figure 2 we plot the regions where β, γ take different values, in the (α, δ) plane.

Before proceeding let us comment on the significance of the parameter $\beta + \gamma$. We

denote[16]

$$\psi = \begin{pmatrix} y_+ \\ z'_- \end{pmatrix}. \tag{3.23}$$

There is a convenient way to recast eq. (3.18) and (3.19) as a second order equation of Schrödinger form, with a spin dependent potential:

$$r^{\gamma+\beta}\partial_r(r^{\gamma+\beta}\partial_r\psi) = \left[m^2 r^{2\beta} + k_1^2 - (\omega + qA_t)^2 r^{2(\beta-\gamma)}\right]\psi + \beta m r^{2\beta+\gamma-1}\sigma_3\psi \tag{3.24}$$
$$+i\left[(\beta - \gamma)r^{2\beta-1}(\omega + qA_t) + qr^{2\beta}\partial_r A_t\right]\sigma_2\psi.$$

The Shrodinger variable is

$$\zeta = \int \frac{dr}{r^{\gamma+\beta}} = \frac{r^{1-\beta-\gamma}}{(1-\beta-\gamma)}. \tag{3.25}$$

The distance as measured in this variable to the horizon ($r = 0$) has a power-law divergence for $\beta + \gamma > 1$, a logarithmic divergence for $\beta + \gamma = 1$ and no divergence for $\beta + \gamma < 1$. This difference yields the interaction strength difference between bulk fermion and black brane. Depending on the distance to the horizon being infinite or finite, it is expected that the influence of the black brane to the bulk fermion is highly suppressed or large. Since at the horizon the bulk fermions decay into black brane degrees of freedom, this distance difference ultimately results in the three qualitatively different types of behaviour (decay ratio width) for the boundary fermions two-point function as we will see below.

Eq. (3.24) is convenient for our analysis for the following reason. We are interesting in the dominant ω dependence at small frequency. As we will see, this dependence arises from a region close to the horizon where the m, A_t dependent terms on the r.h.s. of eq. (3.24) can be neglected. This only leaves the k_1 and ω dependent terms in eq. (3.24). Of these the k_1 dependent term is particularly important, since it is repulsive and hinders the particle from falling into the horizon. Physically this is because the shrinking size of the x, y directions gives rise to a cost in the k_1 dependent energy that increases closer to the horizon. In eq. (3.24) this is seen clearly since the k_1 dependent term does not give rise to a spin dependent potential (which would be proportional to the σ matrices) and only multiplies the identity matrix in spin space, with a sign which corresponds to its providing positive potential energy.

3.1 $\beta + \gamma > 1$

In this case we will see that the WKB approximation can be used to calculate the boundary Green's function. The width of the boundary correlator is related to tunneling through a classically disallowed region in the bulk and will be exponentially suppressed at small frequency.

In the WKB approximation radial derivatives on (y_+, z'_-) are more important than those on the metric or gauge potential, From eq. (3.18) and eq. (3.19) it then follows that

---

[16]In the action eq. (2.4) etc above ψ stands for the four components fermion, in the subsequent discussion we will only be exciting the (y_+, z'_-) components and to save clutter henceforth will refer to the two component spinor itself as ψ.

for example y_+ satisfies the equation,[17]

$$r^{\beta+\gamma}\partial_r(r^{\beta+\gamma}\partial_r y_+) - m^2 r^{2\beta} y_+ - \left(k_1^2 - r^{2(\beta-\gamma)}(\omega + qA_t)^2\right)y_+ = 0. \tag{3.26}$$

We will be mainly interested in the small frequency behaviour, which is essentially determined by the near horizon region, where

$$r \ll 1. \tag{3.27}$$

In this region we see that the mass dependent terms are subdominant compared to the ω and k_1 dependent terms. Also, from eq. (2.7) we see that in this region the gauge potential is given by,

$$A_t \sim r^{1-2\alpha k-2\beta}. \tag{3.28}$$

From eq. (2.22), (2.23) we see that for $\beta + \gamma > 1, (\alpha + \delta)(\alpha - \delta) > 0$. It will turn out that the small frequency behavior can in fact be extracted from the region where

$$r^{1-(2\beta+2\alpha k)} \ll \omega \tag{3.29}$$

so A_t can also be neglected compared to the ω dependence[18] in eq. (3.26). Note that $1 - (2\alpha k + 2\beta) > 0$ under eq. (2.40), therefore eq. (3.27) and (3.29) are compatible.

The equation eq. (3.26) can be cast in the form of a Schrödinger equation for a zero energy eigenstate,

$$-\frac{d^2 y_+}{d\zeta^2} + V y_+ = 0 \tag{3.30}$$

where ζ is defined in eq. (3.25), and V, the potential, is

$$V = k_1^2 - \frac{\omega^2}{r^{2(\gamma-\beta)}}. \tag{3.31}$$

There are three regions of interest in the calculation. The region very close to the horizon, which we will call R_1 is where $r \to 0$. This region is classically allowed, as follows from eq (2.30) which imply that $\gamma - \beta > 0$, therefore $V < 0$.

The second region which we call R_2 is where

$$1 \gg r^{\gamma-\beta} \gg \frac{\omega}{k_1} \tag{3.32}$$

so that the k_1 term dominates over the ω dependent term in V. Note we still have to meet eq. (3.29); at the end of this section we will return to this point and show that eq. (3.29) and eq. (3.32) are indeed compatible. Note that the R_2 region is classically disallowed and in this region the frequency dependence is unimportant.

Finally the third region R_3 is close to the boundary where $r \to \infty$.

The regions R_1 and R_2 are separated by a turning point at

$$r_{tp} = \left(\frac{\omega}{k_1}\right)^{\frac{1}{\gamma-\beta}}. \tag{3.33}$$

_____

[17]This equation has additional terms which are small in the WKB approximation.

[18]We take $q \sim O(1)$.

It is easy to see that in R_1 the solution to eq. (3.30) in the WKB approximation, which corresponds to in-going boundary conditions at the horizon, is

$$y_+ = \frac{1}{\sqrt{\hat{k}}} e^{-i \int \hat{k}(r) dr} \tag{3.34}$$

where

$$\hat{k}(r) = \frac{1}{r^{2\gamma}} \sqrt{\omega^2 - k_1^2 r^{2(\gamma - \beta)}} \,, \tag{3.35}$$

and the constant in the integration is chosen so that $\int \hat{k} dr \simeq \frac{\omega}{(1-2\gamma)r^{2\gamma-1}}$ for $r \to 0$.

In region R_2 there are two independent solutions to eq. (3.30) which in the WKB approximation go like

$$f_{\pm} = e^{\mp \left(\frac{k_1}{(\gamma + \beta - 1) r^{(\gamma + \beta - 1)}} \right)}. \tag{3.36}$$

Matching to eq. (3.34) using standard turning point formulae, see, e.g, [40], gives,

$$y_+ = \frac{A}{\sqrt{\hat{k}}} \left[f_+ + \frac{i}{2} e^{-2I} f_- \right] \tag{3.37}$$

where now

$$\hat{k} = \frac{k_1}{r^{\gamma - \beta}} \,. \tag{3.38}$$

and,

$$I = c_1 \left(\frac{k_1^{2\gamma-1}}{\omega^{\beta + \gamma - 1}} \right)^{\frac{1}{\gamma - \beta}} \,, \tag{3.39}$$

$$c_1 = \int_1^{\infty} \frac{dx}{x^{2\gamma}} \sqrt{x^{2(\gamma - \beta)} - 1} \,, \tag{3.40}$$

and A is an overall coefficient. Notice that e^{-2I} is exponentially suppressed when $\omega \to 0$. Thus the f_- term has a very small coefficient and is subdominant at small ω.

From eq. (3.18), (3.19) it is easy to find the solution for z'_- in this region. The result can be stated as follows. There are two linearly independent solutions in region R_2,

$$\psi_{\pm} = \begin{pmatrix} 1 \\ \mp 1 \end{pmatrix} f_{\pm}. \tag{3.41}$$

The solution which agrees with eq. (3.37) is

$$\psi = \frac{A}{\sqrt{\hat{k}}} \left[\psi_+ + \frac{i}{2} e^{-2I} \psi_- \right] \tag{3.42}$$

Note that in this solution the frequency dependence is summarized in the coefficient e^{-2I}, the solutions, $\psi_{\pm}$ are independent of frequency.

Now $\psi_{\pm}$ can further be extended from region R_2 to region R_3 which lies close to the boundary. Let the coefficients C_1, C_2, eq. (3.14), which arise from $\psi_{\pm}$ be denoted by $C_{1\pm}, C_{2\pm}$ respectively. Then the boundary two-point function is given by

$$G_{R22} = -\frac{C_{2+} + \frac{i}{2} e^{-2I} C_{2-}}{C_{1+} + \frac{i}{2} e^{-2I} C_{1-}} \tag{3.43}$$

A Fermi surface arises when the coefficient C_{1+} vanishes for $\omega \to 0$. In general this imposes one real condition on the momentum k_1 and for a suitably chosen $k_1 = k_F$ and if necessary by adjusting the geometry[19] for the spacetime which interpolates between the near horizon region and the AdS boundary etc it should be possible to meet this condition. By rotational invariance this will then be true for all $|\vec{k}| = k_F$. Expanding C_1 near $k = k_F$ then gives,

$$G_{R22} = \frac{c_3}{\omega - v_F(|\vec{k}| - k_F) + ic_2 e^{-2I}} \tag{3.44}$$

v_F and c_2 arise from the Taylor series expansion of C_{1+} and the leading behaviour of C_{1-}, we have neglected the term proportional to C_{2-} in the numerator, and the leading C_{2+} dependence feeds into the numerator c_3.

We see that the small frequency excitations have a linear dispersion relation, with a width given by,

$$\Gamma \sim e^{-2I} = exp\left[-2c_1 \left(\frac{k_F^{2\gamma-1}}{\omega^{(\beta+\gamma-1)}}\right)^{\frac{1}{\gamma-\beta}}\right]. \tag{3.45}$$

This width is exponentially suppressed at small frequency and therefore very narrow.

Let us end by checking the validity of our approximations. Our use of the WKB approximation in regions R_1, R_2 imposes restrictions. This approximation requires that radial derivatives acting on $\psi = \begin{pmatrix} y_+ \\ z'_- \end{pmatrix}$ are more important than derivatives of the metric. In region R_2 this gives the condition

$$r^{\gamma+\beta-1} \ll 1 \tag{3.46}$$

(we have set $k_1 \sim O(1)$). Note that eq. (3.46) can be met in the near horizon geometry where $r \ll 1$ only if $\beta + \gamma > 1$. The fact that the WKB approximation breaks when $\beta + \gamma \le 1$ is also suggested by the decay width eq. (3.45) which is no longer suppressed at small ω. In addition, we have assumed that eq. (3.29) is correct so that the gauge potential dependent terms can be dropped. In region R_2 this has to be compatible with the condition eq. (3.32). One can show from eq. (2.22), eq. (2.23) that in the region where $\beta + \gamma > 1$, $\gamma - \beta < 1 - (2\beta + 2\alpha k)$, it therefore follows that for small ω these two conditions are compatible.

In Region R_1 far from the turning point validity of WKB approximation requires,

$$r \ll \omega^{\frac{1}{2\gamma-1}} \tag{3.47}$$

In addition eq. (3.29) needs to be met. These are clearly compatible, in fact eq. (3.47) is more restrictive.

3.2 Some general comments for the cases $\beta + \gamma \le 1$

We will now turn to analyzing what happens when $\beta + \gamma \le 1$.

---

[19]One can also vary the dilaton dependence of the gauge coupling and potential once the dilaton is not in the run-away region.

A few general comments are worth making before we go into details. From eq. (2.22), eq. (2.23) we see that $\beta + \gamma = 1$ corresponds to the lines, $\alpha = -\delta$ and $\alpha = +\delta$. The first case, $\alpha = -\delta$ corresponds to an $AdS_2 \times R^2$ metric which is the near-horizon geometry of the extreme Reissner Nordstrom Black Brane. This has been analyzed extensively in [4]–[9], and we will not elaborate on this case further. The second case, $\alpha = \delta$, necessarily has $\beta \neq 0$ (for $\alpha \neq 0$), it is not $AdS_2 \times R^2$ and has vanishing area.

In the extremal RN case while studying the fermion equation of motion eq. (3.18), eq. (3.19) at small frequency the dependence on m, k_1 and charge through A_t dependent terms are all important. In contrast for the $\alpha = \delta$ case and for all cases where $\beta + \gamma < 1$ both the A_t and m dependent terms in eq. (3.18), (3.19) can be neglected, in the near-horizon region relevant for determining the small frequency behaviour. This results in considerable simplification of the analysis.

It turns out that extracting the ω dependence requires us to solve the equations from the horizon upto a radial location where

$$1 \gg r \gg \omega^{\frac{1}{2\gamma-1}}. \tag{3.48}$$

Beyond that the ω dependence turns out to be subdominant and can be neglected.[20] Now from eq. (3.18), (3.19) we see that the A_t dependence is unimportant if $|A_t| \ll \omega$. From eq. (3.29) this leads to the condition,

$$r \ll \omega^{\frac{1}{1-2\alpha k-2\beta}} \tag{3.49}$$

which is compatible with eq. (3.48) if

$$\omega^{\frac{1}{2\gamma-1}} \ll \omega^{\frac{1}{1-2\alpha k-2\beta}}. \tag{3.50}$$

This last condition is true for $\omega \ll 1$ because eq. (2.22), eq. (2.23) imply that $2\gamma - 1 < 1 - 2\alpha k - 2\beta$ for $\delta \neq -\alpha$.

The m dependent terms can be neglected if they are small compared to the effect of ∂_r. Now ψ will be vary at least as rapidly as a power of r, from eq. (3.18), (3.19) the condition for neglecting the m dependent term then becomes

$$\frac{m}{r^\gamma} \ll \frac{1}{r}. \tag{3.51}$$

For $m \sim O(1)$, $r \ll 1$ this gives, $\gamma < 1$, which is true since $\beta + \gamma \leq 1$ and $\beta > 0$ when $\alpha \neq -\delta$.

Henceforth we will study the cases $\beta + \gamma < 1$ and the branch $\alpha = \delta$ for the case $\beta + \gamma = 1$ and therefore we can set the A_t, m dependent terms to be zero in[21] eq. (3.18), eq. (3.19).

---

[20]One expects on general grounds that the gravitational redshift is monotonic as one goes from the black brane horizon to the boundary making the ω dependence increasingly negligible.

[21]To ensure clarity let us reiterate that below when we refer to $\beta + \gamma = 1$ we only mean the case where $\alpha = \delta$, for which the metric is not $AdS_2 \times R^2$.

Eq. (3.18), (3.19) then become, in terms of

$$\psi = \begin{pmatrix} y_+ \\ z'_- \end{pmatrix}, \tag{3.52}$$

$$r^{\beta+\gamma}\partial_r\psi = (-k_1\sigma_1 + ir^{\beta-\gamma}\omega\sigma_2)\psi. \tag{3.53}$$

The behaviour of the solution can be understood qualitatively as follows. Very close to the horizon, the ω dependent term on the r.h.s. will dominate over the k_1 dependent one since $\beta - \gamma < 0$ as eq. (2.30). Thus ψ will be of the form given in eq. (3.21). The effects of the frequency will become subdominant to k_1 dependent ones when the ω dependent term on the r.h.s. of eq. (3.53) becomes less important compared to the k_1 dependent term giving the condition,

$$r \gg \left(\frac{\omega}{k_1}\right)^{\frac{1}{\gamma-\beta}}. \tag{3.54}$$

Now another way to estimate when the effects of frequency become small is when the the phase in eq. (3.21) becomes small. Using eq. (3.22) this gives

$$|\omega z| \sim |\frac{\omega}{r^{2\gamma-1}}| \ll 1 \tag{3.55}$$

which implies,

$$r \gg \omega^{\frac{1}{2\gamma-1}}. \tag{3.56}$$

Now it is easy to see that for $\beta + \gamma < 1$, $\omega^{\frac{1}{2\gamma-1}} < \omega^{\frac{1}{\gamma-\beta}}$ for $\omega \ll 1$. Thus as r is increased from the horizon eq. (3.56) will be met before eq. (3.54) is met.[22] For the case when $\beta + \gamma < 1$ then in the region where

$$\omega^{\frac{1}{2\gamma-1}} \ll r \ll \left(\frac{\omega}{k_1}\right)^{\frac{1}{\gamma-\beta}} \tag{3.57}$$

the solution can be obtained by simply expanding the exponential in eq. (3.21) and gives,

$$\psi = \begin{pmatrix} 1 \\ -i \end{pmatrix} + O(\omega z). \tag{3.58}$$

Going to large values of r the k_1, m and A_t dependence will become important, but in this region the ω dependence can be neglected. We will return to studying the consequences of our analysis above for the $\beta + \gamma < 1$ case in section 3.4.

In contrast, for the $\beta + \gamma = 1$ case the two exponents in eq. (3.54) and (3.56) are the same, since $\beta = 1 - \gamma$. Thus, the k_1 dependence will become important before the phase factor in eq. (3.21) can be approximated to unity. Going to large values the k_1 dependent term will be more important and the solution will take the form,

$$\psi = d_1 \begin{pmatrix} 1 \\ -1 \end{pmatrix} r^{k_1} + d_2 \begin{pmatrix} 1 \\ 1 \end{pmatrix} r^{-k_1}. \tag{3.59}$$

At even large values of r the A_t, m dependent terms will also get important. We will turn to a more complete analysis of this case in section 3.3.

---

[22]We are assuming k_1 is $O(1)$ here.

3.3 More on the $\beta + \gamma = 1$ case

Here we will be interested in solving the fermion equation in the background, eq. (2.22), eq. (2.23), with $\alpha = \delta$.

Our starting point is eq. (3.53). It is convenient to define,

$$\chi_\pm = y_+ \pm z'_-. \tag{3.60}$$

And work with the variable,

$$\tilde{z} = \frac{\omega}{(2\gamma - 1)r^{2\gamma - 1}}, \tag{3.61}$$

which goes to infinity at the horizon. For now we specialize to the case when $k_1 > 0$ and define

$$\eta = \frac{k_1}{2\gamma - 1}. \tag{3.62}$$

Then eq. (3.53) becomes,

$$(\tilde{z}\partial_{\tilde{z}} - \eta)\chi_+ = \tilde{z}\chi_- \tag{3.63}$$

$$(\tilde{z}\partial_{\tilde{z}} + \eta)\chi_- = -\tilde{z}\chi_+, \tag{3.64}$$

which gives the second order equation,

$$\left[\tilde{z}^2\partial_{\tilde{z}}^2 + (\tilde{z}^2 - \eta^2 - \eta)\right]\chi_- = 0. \tag{3.65}$$

The solution for χ_- with the ingoing boundary conditions at the horizon is then

$$\chi_- = \sqrt{\tilde{z}}H_{\frac{1}{2}+\eta}^{(1)}(\tilde{z}), \tag{3.66}$$

and from eq. (3.64) for χ_+ is

$$\chi_+ = -\tilde{z}^{-\eta}\partial_{\tilde{z}}(\tilde{z}^\eta\chi_-). \tag{3.67}$$

As discussed in appendix D in the region where $\tilde{z} \ll 1$, i.e., $\omega \ll r^{2\gamma - 1}$, the solution for $\psi = \begin{pmatrix} y_+ \\ z'_- \end{pmatrix}$, in terms of the radial variable r and upto an overall ω dependent normalization which is not important, becomes

$$\psi = \begin{pmatrix} 1 \\ -1 \end{pmatrix}r^{k_1} + de^{i\phi}\omega^{2\eta}\begin{pmatrix} 1 \\ 1 \end{pmatrix}r^{-k_1}. \tag{3.68}$$

Here d and the phase $e^{i\phi}$, which in general has both a real and imaginary part, depend on γ, β, k_1, but are independent of ω.

Actually, as noted in appendix D, this solution is only valid when $\eta < 1/2$. For the case $\eta > 1/2$ the solution takes the form

$$\psi = \begin{pmatrix} 1 \\ -1 \end{pmatrix}r^{k_1} + id'\omega^{2\eta}\begin{pmatrix} 1 \\ 1 \end{pmatrix}r^{-k_1}, \tag{3.69}$$

so that the second term on the r.h.s. makes a contribution only to the imaginary part of ψ. There are subleading corrections on the r.h.s. to the real part of ψ which are suppressed

by a power of ω, these are not kept in eq. (3.69) since their effect on the Green's function is comparable to ω dependent contributions generated when evolving the solution further out towards the boundary.

Note that the result eq. (3.68), eq. (3.69) agrees with eq. (3.59) above. It is also worth commenting that the result eq. (3.68), eq. (3.69) agrees with what one would get by continuing the WKB results of section 3.1 to the case $\beta + \gamma = 1$. More precisely, from eq. (3.25) we see that for $\beta + \gamma = 1$, $\zeta = \log r$. As a result for $r \gg r_{tp}$ the exponential factor in the two solutions go like[23] $r^{\pm k_1}$ which agrees with eq. (3.68), eq. (3.69). The solution which grows, as r increases, has wavefunction $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$ in the two component $\begin{pmatrix} y_+ \\ z'_- \end{pmatrix}$ space and the falling solution has wave function $\begin{pmatrix} 1 \\ 1 \end{pmatrix}$, just as in the WKB case. The only difference is that the WKB suppression factor which was exponentially suppressed in ω has now turned into a power-law suppression in eq. (3.68), eq. (3.69). This is because the fermion wave function can now penetrate the barrier more easily and thus can have a bigger mixing with the modes in the vicinity of the horizon. This crossover from the exponential suppression to a power-law has also been discussed in [18].

So far for ease of discussion we have considered the case when $k_1 > 0$. For the case $k_1 < 0$ a very similar analysis can be carried out, as discussed in appendix D. Let us define η, both for the case when $k_1 > 0$ and $k_1 < 0$ to be

$$\eta = \frac{|k_1|}{2\gamma - 1}, \tag{3.70}$$

so that $\eta > 0$. Now for $k_1 < 0$ and $\eta < 1/2$, the solution eq. (3.68) is replaced by

$$\psi = \begin{pmatrix} 1 \\ 1 \end{pmatrix} r^{|k_1|} + d e^{i\phi} \omega^{2\eta} \begin{pmatrix} 1 \\ -1 \end{pmatrix} r^{-|k_1|}. \tag{3.71}$$

And for $k_1 < 0$, $\eta > 1/2$, eq. (3.69) is replaced by

$$\psi = \begin{pmatrix} 1 \\ 1 \end{pmatrix} r^{|k_1|} + i d' \omega^{2\eta} \begin{pmatrix} 1 \\ -1 \end{pmatrix} r^{-|k_1|}. \tag{3.72}$$

It is now easy to follow the discussion in section 3.1 to calculate the two-point function on the boundary in this case. A Fermi surface will arise for $k_1 = k_F$ if the growing solution (this is the first term on the r.h.s. of eq. (3.68), (3.71) for this value of k_1 is purely normalisable in AdS_4. The Green's function one gets by expanding around this value of momentum is

$$G_{R22} = \frac{Z}{\omega - v_F(|k| - |k_F|) + i D e^{i\phi} \omega^{2\eta}} \tag{3.73}$$

where Z, D are constants. For $\eta > 1/2$, the phase $e^{i\phi} = 1$, whereas for $\eta < 1/2$ the phase is in general complex.

---

[23]There is also a prefactor $\frac{1}{\sqrt{k}}$ which gives rise to an additional powerlaw in r. We are not keeping this term.

This result is very similar to what was obtained in the eRN case in [4–7]. The result also agrees with the general considerations in[24] [23].

For $\eta > 1/2$ there is a well-defined quasi-particle with a linear dispersion and a width which goes like $\omega^{2\eta}$. For $1/2 < \eta < 1$, the width is broader than the Fermi liquid case. For $\eta < 1/2$ the behaviour is more novel. The last term in the denominator going like $\omega^{2\eta}$ dominates both the real and imaginary parts of the ω dependence. As a result there is no well-defined quasi-particle, since the residue vanishes at the pole. Finally for $\eta = 1/2$, as discussed in appendix D the Green's function actually needs to be modified and takes the form,

$$G_{R22} = \frac{Z}{v_F(|k| - |k_F|) + d_1 \omega \log \omega + d_2 \omega} \tag{3.74}$$

where d_1 is real and d_2 complex.

Unlike the eRN case, when $\alpha = \delta$ and $\gamma \neq 1$, the geometry has no scaling symmetry. Despite this fact eq. (3.53) has a scaling symmetry for all values of γ, when $\beta + \gamma = 1$, under which $r \rightarrow \lambda r, \omega \rightarrow \lambda^{2\gamma-1}\omega$ with k_1 being invariant.[25] This scaling symmetry results in the the complex part characterized by the exponent η being of power law type in the frequency. One difference is that in our case the mass and charge of the bulk fermion do not enter in η explicitly but only through k_F, which does depend on these parameters.

Before closing this subsection it is worth commenting that while on general grounds we expect a value of k_F to exist for which the bulk solution is purely normalisable, leading to a singularity in G_{R22}, we have not investigated this feature in detail, e.g., in the solutions discussed in appendix F which are asymptotically AdS_4. We leave such an analysis, along with the related calculation of Z, v_F, D which appear in eq. (3.73), for the future.

3.4 Case $\beta + \gamma < 1$

In this case the essential features of the solution can be deduced by setting the k_1 dependent terms in eq. (3.53) to zero. This can be seen to be self-consistently true. In fact the essential point was already made in section 3.2. Setting the k_1 dependent term to vanish in eq. (3.53) gives the solution eq. (3.21). When eq. (3.55) is met the solution reduces to (3.58). This happens before the k_1 term becomes important because

$$\omega^{\frac{1}{2\gamma-1}} \ll \omega^{\frac{1}{\gamma-\beta}} \tag{3.75}$$

when $\beta + \gamma < 1$ as discussed in section 3.2 around eq. (3.57).

The reader might worry that this argument is a bit too quick. We will examine it more carefully in appendix C and find that it is indeed justified. The more careful analysis shows that the region eq. (3.57) where the solutions reduces to the form, eq. (3.58) should be thought of as being obtained by keeping $r/\omega^{1/(2\gamma-1)}$ fixed and large while taking $\omega \rightarrow 0$.

Let us now examine the consequences of eq. (3.58). Note in particular that at leading order y_+ and z'_- have a relative phase which is imaginary.

---

[24]In fact eq. (3.73), for $\eta < 1/2$, is of the scaling form proposed in [23] and satisfies the inequalities in eq. (9) and (18) of [23].
[25]In fact a suitable change of variables can map the eq. (3.53) for all values of γ, and $\gamma + \beta = 1$, to the case $\gamma = 1, \beta = 0$.

In the following discussion it will be useful at this stage to to define two basis vectors,

$$\psi_+ = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \psi_- = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \tag{3.76}$$

and express the leading order answer as

$$\begin{pmatrix} y_+ \\ z'_- \end{pmatrix} = \psi_+ - i\psi- \tag{3.77}$$

Starting from the region eq. (3.57) and going further towards the boundary the k_1, m, A_t dependent terms we have been neglecting will come into play and the form of the solution will deviate from eq. (3.77). Asymptotically, towards the boundary, the solution obtained from both $\psi_\pm$ will take the form given in eq. (3.14). Let $C_{1\pm}, C_{2\pm}$ be the values for the coefficients $C_{1,2}$ which appear in eq. (3.14) when we start with $\psi_\pm$ and evolve the solution towards the boundary respectively. Then, the net value of C_1 we get starting from eq. (3.77) is

$$C_1 = C_{1+} - iC_{1-} \tag{3.78}$$

Now notice that the equations eq. (3.18), eq. (3.19) are both real, therefore $C_{1\pm}$ will be both real as well.

As in the discussion for the $\beta + \gamma > 1$ case a Fermi surface arises at $k_1 = k_F$ when C_1 vanishes at this momentum as $\omega \to 0$. However, since C_{1+} and C_{1-} are real this actually imposes two conditions

$$C_{1+} = 0 \,, \, C_{1-} = 0 \tag{3.79}$$

which must both be met by adjusting only one real variable - the momentum k_1. Generically, this will be impossible to do.

Our conclusions will be discussed more throughly in the following subsection. We will see that starting from $\beta + \gamma = 1$ as we go into the region where $\beta + \gamma < 1$, there is no locus in momentum space about which there are quasi-particle excitations with a width that vanishes as ω vanishes. However, for $\beta + \gamma < 1$, but close to unity, there is a surface about which the excitations have a frequency independent width (at small ω) which is much smaller than the chemical potential and which vanishes as $\beta + \gamma \to 1$.

Let us close by again mentioning that the approximations made in the analysis above of neglecting the k_1 dependent terms is examined more carefully in appendix C and found to be indeed valid.

3.5 The transition from $\beta + \gamma = 1$ to $\beta + \gamma < 1$

It is useful to discuss the transition from $\beta + \gamma = 1$ to $\beta + \gamma < 1$ in more detail.

Let us start with the case $\beta + \gamma = 1$ and first consider the case when the exponent η in eq. (3.73) satisfies the condition $2\eta > 1$. In this case, at small ω,

$$G_{R22} = \frac{Z}{\omega - v_F(|k| - k_F) + id_1\omega^{2\eta}}, \tag{3.80}$$

and as was mentioned above there are well-defined quasi-particle excitations about the Fermi surface.

Suppose we now lower the value of $\beta + \gamma$ so that $\beta + \gamma = 1 - \epsilon, \epsilon \ll 1$. The bulk fermion solution with momentum k_F will not be purely normalisable any more and our arguments in the previous subsection show that the Green's function takes the form,

$$G_{R22} = \frac{Z}{\omega - v_F(|k| - k_F) + \Delta_1 + i\Delta_2 + id_2\omega^{2\eta}} \qquad (3.81)$$

where Δ_1, Δ_2, are ω independent and vanish when $\epsilon \to 0$. We see that Δ_1 can be absorbed by a shift in[26] k_F, $k_F \to k_F - \frac{\Delta_1}{v_F}$. About this new Fermi momentum we get,

$$G_{R22} = \frac{Z}{\omega - v_F(|k| - k_F) + i\Delta_2 + id_2\omega^{2\eta}} \qquad (3.82)$$

so that the excitations have a width Δ_2, which does not vanish as $|k| \to k_F, \omega \to 0$, and is therefore very broad. In summary, the well-defined quasi-particle which existed at $\beta + \gamma = 1$ has therefore disappeared at $\beta + \gamma < 1$.[27]

Next, let us turn to the case when the exponent η in eq. (3.73) satisfies the condition $2\eta < 1$. In this case there is no sharply defined quasi-particle even when $\beta + \gamma = 1$. We define,

$$k_T \equiv (|k| - k_F). \qquad (3.83)$$

Taking $|k_T|$ fixed and small compared to k_F, and regarding G_{R22} as a function of ω there is a pole [9] at $\omega = \omega_* + i\Gamma$ with

$$\omega_* \sim \Gamma \sim |k_T|^{\frac{1}{2\eta}}. \qquad (3.84)$$

The pole has vanishing residue,

$$Z_{\text{res}} \to 0, \qquad (3.85)$$

and is also broad,

$$\frac{\Gamma}{w_*} \to 1, \qquad (3.86)$$

as $k_T \to 0$.

Let us now lower $\beta + \gamma$ in this case to the value $\beta + \gamma = 1 - \epsilon$. This results[28] in a Green's function,

$$G_{R22} = \frac{Z}{-v_F(|k| - k_F) + \Delta_1 + i\Delta_2 + De^{i\phi}\omega^{2\eta}}, \qquad (3.87)$$

where $\Delta_{1,2}$ vanish as $\epsilon \to 0$. Shifting k_F this can be written as

$$G_{R22} = \frac{Z}{-v_F(|k| - k_F) + |\Delta|De^{i\phi}e^{-i\pi\eta} + De^{i\phi}\omega^{2\eta}} \qquad (3.88)$$

---

[26]Alternatively, e.g., in the canonical ensemble, we can absorb it into a shift in the chemical potential μ.

[27]The width Δ_2, while it does not vanish when $|k| \to k_F$, is small compared to the chemical potential for $\epsilon \ll 1$.

[28]The term linear in ω in the denominator is dropped compared to $\omega^{2\eta}$ at small ω.

where $|\Delta|$ is determined by Δ_1, Δ_2 and the shift in k_F. For $|k| \to k_F$ the pole in ω lies at

$$\omega_* = -i|\Delta|. \tag{3.89}$$

This gives rise to a width which does not vanish when $(k - k_F) \to 0$.

In summary we see that when $\beta + \gamma < 1$ the excitations become very broad and acquire a width which is non-vanishing at zero frequency. There is still a locus in momentum space, at $|k| = k_F$, which we can call the Fermi surface, with the energy of the excitations, defined as the real part of ω, extending down to zero energy as the momentum approaches k_F. However, a more precise definition of the Fermi surface can be taken to be the locus where Green's function with $\omega = 0$ has a pole in momentum, and across which it changes sign. With this definition, there is no Fermi surface for $\beta + \gamma < 1$, since the excitations have a non-zero width even at zero energy, as mentioned above.[29]

4 Conclusions

The gravity system studied in this paper has a scalar, the dilaton, and two couplings α and δ which appear in the action given in eq. (2.2), (2.3) and which determine how the dilaton enters in the gauge coupling and the potential respectively. Instead of α, δ it is sometimes more convenient to use the parameters, β, γ, which appear in the metric eq. (2.13) and are given in terms of α, δ, in eq. (2.22), (2.23).

Extremal black branes in this system were studied in [15]. Here we have studied a charged fermion in the extremal black brane background and calculated the two-point function for the corresponding fermionic operator in the dual strongly coupled field theory. The black brane background has rotational symmetry in the two spatial directions and the two-point function inherits this symmetry, At small frequency, which is the focus of our investigation, the essential features of this two -point function can be deduced from the near-horizon geometry of the extremal black hole.

4.1 Results

Our results depend on the parameters β, γ, in particular on the combination[30] $\beta + \gamma$.

- When $\beta + \gamma > 1$ we find that close to the Fermi-surface there are well-defined quasi-particles, with a linear (i.e. relativistic) dispersion relation and a width which is exponentially suppressed in ω. The precise form of the Green's function is given in eq. (3.44).

- This behaviour undergoes a transition when $\beta + \gamma < 1$. In this case there are no well-defined quasi-particle excitations. Instead the low-energy excitations become very broad with a width which does not vanish at small frequency. See the concluding paragraph of section 3.5 for more discussion on the Fermi surface.

---

[29]We thank Mohit Randeria for explaining this definition of the Fermi surface and for related discussion.
[30]The distance to the horizon for the variable ζ, eq. (3.25), in terms of which the fermion equation of motion becomes of Schrödinger form is governed by $\beta + \gamma$. It is infinite for $\beta + \gamma > 1$, logarithmically infinite for $\beta + \gamma = 1$, and finite for $\beta + \gamma < 1$.

- The transition region $\beta + \gamma = 1$ is also very interesting. In terms of the parameters α, δ which appear in the Lagrangian for the system, this corresponds to two lines, $\alpha = \pm\delta$. The $\alpha = -\delta$ line corresponds to an extremal RN geometry. The fermionic two-point function in this case is well studied and known to exhibit interesting non-Fermi liquid behaviour. Here we focus on the other case, the $\alpha = \delta$ line, for which the extremal geometry has vanishing entropy and the near-horizon geometry has no scaling symmetry. Despite this difference we find that bulk fermion equation acquires a scaling symmetry analogous to that in the eRN case and the two-point function again exhibits non-Fermi liquid behaviour. The precise form of the Green's function is given in eq. (3.73) and depends on the parameter η. When $2\eta < 1$, there are no well-defined quasi-particles excitations close to the Fermi surface. When $2\eta > 1$, there are well-defined quasi-particle, with a width which vanishes as $\omega \to 0$, although this width can be much broader than in Fermi-liquid theory. When $2\eta = 1$, one gets a marginal Fermi liquid.[31] The quasiparticles, when they exist for the $\beta + \gamma = 1$ case, get very broad when $\beta + \gamma$ becomes less than unity.

- The transition between these behaviours occurs in a smooth way. More precisely, the Green's function evolves in a smooth manner as the parameter $\beta + \gamma$ is varied. The underlying reason for this is that the background geometry itself evolves smoothly.

4.2 Discussion

It is worth trying to phrase our results in terms of the semi-holographic description which was proposed in [18]. The near-horizon region of the geometry corresponds to a strongly coupled field theory sector in this description, which is coupled to bulk fermionic excitations localized away from the near-horizon region. The bulk fermionic excitations by themselves are weakly coupled and form a sea which is essentially responsible for the Fermi surface in the boundary theory. The coupling between the two sectors allows the bulk fermions to decay and gives rise to their width. When $\beta + \gamma > 1$ this decay width is small, since it arises due to tunneling through a WKB barrier. This results in a width which is highly suppressed with an essential singularity as $\omega \to 0$. As $\beta + \gamma \to 1$ the barrier is lowered and the bulk fermions can decay more easily into degrees of freedom in the strongly coupled sector, resulting in a decay width which is only power law suppressed. Finally, when $\beta + \gamma < 1$ the decay process is sufficiently enhanced and leads to a width which is non-vanishing even as $\omega \to 0$, leaving no sharply defined quasi-particles in the excitation spectrum.

In fact in our analysis we did not use the information about the full geometry but only the geometry in the near-horizon region. The full geometry depends on many more details of the model including the dependence, even away from the run-away region where $\phi \to \pm\infty$, of the gauge coupling function and the potential on the dilaton. It is therefore less universal than the near-horizon geometry which is in fact often an attractor. This is very much in the spirit of the semi-holographic description, in effect we only relied on the gravity dual for the strongly coupled sector, and did not use much information about the gravity

---

[31]One difference with the eRN case is that the mass and charge of the bulk fermion enters in η only through their dependence on the Fermi-momentum, k_F.

solution away from the horizon since in the end that would have given rise to a weakly coupled bulk fermion whose dynamics can be understood in field theoretic terms anyways.[32]

The basic lesson then from this paper is that a range of interesting behaviours can arise by coupling fermions to a strongly coupled sector with a gravitational dual of the kind considered here. This includes both Fermi liquid and non-Fermi liquid behaviour, transitions between them, and transitions from a non-Fermi liquid state to one where there are no well-defined quasi-particles since the excitations have become very broad and essentially disappeared. Moreover, this can happen when the strongly coupled sector has reasonable thermodynamics behaviour consistent in particular with the third law of thermodynamics, since the gravity background has vanishing entropy at extremality.

An important feature about our system is that the dramatic changes in the behaviour of the fermionic Green's function which we have found are *not* accompanied by any phase transition or significant changes in the thermodynamics or transport properties. The entropy densty or specific heat, for example, scale as given by eq. (2.38) and smoothly changes as $\beta + \gamma$ is lowered from a value greater than unity to less than unity. Similarly, the DC or optical conductivity also changes smoothly, eq. (2.57), eq. (2.56), eq. (2.58). In fact the background geometry itself changes smoothly, as was mentioned above, this is the root cause for the smooth behvaiour in transport and conductivity. On general grounds the gravity system should correspond to a strongly coupled field theory in the large N limit. In this limit there are many extra degrees of freedom besides the fermionic ones we have focussed on. And these extra degrees of freedom do not undergo any significant change in their properties even though the fermionic ones we have focussed on do, resulting in the smooth changes in thermodynamics and transport.

The large N limit is the price we pay for the having a tractable gravity description. At finite N one would expect that the transitions seen in the behaviour of the fermion correlator will also manifest itself in phase transitions or big qualitative changes in thermodynamics and transport. Preliminary evidence for this is the fact that the conductivity in our set up already has $1/N$ corrections which see the changes in the nature of the fermion two-point function. This was investigated in [8, 9], where it was found that for a Green's function of the type in eq. (3.73) there would be corrections to conductivity of the form $\sigma \sim \frac{1}{N} T^{-2\eta}$. Since we have found non-Fermi liquid behaviour to arise from in a wide variety of gravitational backgrounds it is reasonable to hope that it will persist for some finite N strongly coupled theories as well.

There are several directions for future work. It will be interesting to generalize the investigations of this paper to higher dimensions.[33]

Going beyond effective field theory, it is important to try and embed the class of gravity systems studied here in string/M theory. This would put constraints on allowed values of α, β and also the charges and masses for the Fermion fields which determine k_F

---

[32]Some examples of gravity solutions which interpolate between AdS_4 and the solution eq. (2.13) in the near-horizon region are discussed in appendix F. These are obtained with reasonable potentials and gauge coupling functions. It is worth studying these examples further to calculate the value of k_F (for $\beta + \gamma \geq 1$) and the the value of the residue and v_F in eq. (3.73), (3.82), (3.88), in them.

[33]See for example [41].

and the exponent η in eq. (3.73). Allowed ranges of these parameters would then determine which kinds of non-Fermi liquid theories are theoretically speaking allowed and when transitions of various kinds are allowed. Embedding in string/M theory is also important for deciding whether our approximation of classical two -derivative gravity is a controlled one, as was discussed in section 2.4. For some progress towards providing such embeddings see [42, 43].[34] It will also be useful to ask whether this analysis can be extended beyond the case where the gravity theory is analyzed in the two-derivative approximation for example in Vasiliev theory [44].

Another direction would be to couple charged matter and study superconducting instabilities [45] along the lines of [11]. Or to allow for a bulk Fermi sea in the near-horizon region and incorporate the changes this leads to [27, 46, 47].[35]

Investigating transitions of the kind we have found in the presence of a magnetic field would also be an interesting extension. In this context it would be natural to also include an axion in the bulk theory, [14].

Finally, only a very small class of possible attractor geometries have been studied here.[36] There is clearly a vast zoo waiting to be explored and the behaviour of fermions in these additional backgrounds might hold even more surprises.

We leave these directions for the future.

Acknowledgments

A   Other near-horizon geometries

In this appendix we discuss another kind of near-horizon extremal solution which is obtained from the equations of motion and is also consistent with the ansatz, eq. (2.13). The

---

[34]For example, our IR effective action (2.1) with parameter $\alpha = \sqrt{3}, \delta = -1/\sqrt{3}, V_0 = -12\sqrt{3}$ can be obtained from M-theory on Sasaki-Einstein space from eq. (4.3) of [42], by setting $\chi = 0$ and $h \equiv \pm 1 \mp e^{4\phi/\sqrt{3}}$, in the regime where $|e^{4\phi/\sqrt{3}}| \ll 1$. However, the near horizon behaviour of the numerically obtained solution in [42] is different from our solution (2.22), (2.23). It is worth studying this point further, we thank J. Gauntlett, J. Sonner and T. Wisemann for a discussion.

[35]We thank S. Minwalla and S. Hartnoll for a discussion on this point.

[36]Some references pertaining to the attractor mechanism are, [28, 48–53], and more recently [54].

essential idea is to meet eq. (2.10) and eq. (2.9) as in eq. (2.14), eq. (2.15), eq. (2.16). However, eq. (2.11), eq. (2.12) are now met by assuming that

$$2\beta < -k(\alpha + \delta) \tag{A.1}$$

so that the l.h.s. in eq. (2.17), eq. (2.18) is more important at small r than the r.h.s. This yields the equations,

$$k^2 = \beta(1 - \beta) \tag{A.2}$$

$$C_a^2(1 + \beta + k\delta)(1 + 2\beta + 2k\delta) = -V_0 \tag{A.3}$$

$$\gamma - 1 = \delta k \tag{A.4}$$

$$2C_a^2 k(1 + 2\beta + 2k\delta) = \delta V_0 \tag{A.5}$$

$$C_a^2 \beta(1 + 2\beta + 2k\delta) = -\frac{1}{2}V_0 \tag{A.6}$$

The solution is

$$\beta = \frac{1}{1 + \delta^2} \quad \gamma = \frac{1}{1 + \delta^2} \quad k = -\frac{\delta}{1 + \delta^2} \quad C_a^2 = -V_0\frac{(1 + \delta^2)^2}{2(3 - \delta^2)} \tag{A.7}$$

This is valid for those values of (α, δ) which satisfy the conditions,

1. $2 < \delta(\alpha + \delta)$ and

2. $\delta^2 < 3$.

The first of these conditions, arises from eq. (A.1).

Let us describe the solution discussed in section 2 as Case(1), and the solution discussed in this appendix as Case(2). For a fixed α (> 0) and δ small, we are in region where Case(1) is valid. If we then increase δ, this solution breaks down when Q_e^2 turns negative (i.e $\delta(\alpha + \delta) = 2$), and we enter into the region where Case(2) becomes valid.

B More on conductivity

Here we provide some details for the calculation of the conductivity. The metric in the near horizon extremal geometry is

$$ds^2 = -C_a^2 r^{2\gamma}dt^2 + \frac{dr^2}{C_a^2 r^{2\gamma}} + r^{2\beta}(dx^2 + dy^2) \tag{B.1}$$

with $e^\phi = r^k$ and the gauge field being

$$F = \frac{Q}{r^{2\alpha k + 2\beta}}dt \wedge dr. \tag{B.2}$$

The constants, $\gamma, \beta, C_a^2, Q^2$, are given in eq. (2.22) and (2.23).

Comparing with [13] eq. (3.3)

$$ds^2 = -g(\hat{r})e^{-\chi(r)}dt^2 + \frac{d\hat{r}^2}{g(\hat{r})} + \hat{r}^2(dx^2 + dy^2), \tag{B.3}$$

we have,

$$\hat{r} = r^{\beta} \tag{B.4}$$

$$g(\hat{r}) = C_a^2 \beta^2 \hat{r}^{\frac{2}{\beta}(\beta+\gamma-1)} \tag{B.5}$$

$$e^{\chi(\hat{r})} = \beta^2 \hat{r}^{2\left(1-\frac{1}{\beta}\right)} . \tag{B.6}$$

The Schrödinger variable defined in eq. (3.8) of [13], also eq. (2.52) above, is then,

$$z = -\frac{1}{(2\gamma-1)C_a^2} \frac{1}{r^{2\gamma-1}} = -\frac{1}{(2\gamma-1)C_a^2} \frac{1}{\hat{r}^{\frac{2\gamma-1}{\beta}}} . \tag{B.7}$$

The horizon lies at $r \to 0$ or $z \to -\infty$. The Schrödinger potential is as given in eq. (3.15) of [13]

$$V(z) = \left(\frac{f''}{f} + 16 \frac{ge^{-\chi}}{f^2} \frac{Q^2}{r^4} \right) \tag{B.8}$$

where $f = 2e^{\alpha\phi}$. Note the factor of 16 which was not there in [13] eq. (3.15). This is because their convention for Q differs from our Q by a factor of 4. This can be seen by comparing eq. (3.14) of [13] with eq. (B.2). Plugging in the values of k, γ, C_a, Q from eq. (2.22) and eq. (2.23), we get

$$V = \frac{2}{z^2} \frac{(4+\alpha^2-\delta^2)(4+(\alpha-2\delta)(\alpha+\delta))}{(4+(\alpha-3\delta)(\alpha+\delta))^2}, \tag{B.9}$$

leading to c as given in eq. (2.54) above.

C Neglecting the k_1 dependent terms

Most of this appendix will deal with a more careful analysis justifying our neglect of the k_1 dependent terms in eq. (3.53) in section 3.4. However, before we embark on that discussion let us note the following. We had argued after eq. (3.79) that generically the two conditions required for the existence of a Fermi surface will not be met by tuning just k_1 which is one real variable. However, one might have a lingering doubt as to whether this non-genericity is built into the very nature of eq. (3.18), (3.19) and follows perhaps from its symmetries. We will now set this doubt to rest.

The equations eq. (3.18), (3.19) are invariant under an exchange of $y_+ \leftrightarrow z'_-$ accompanied by a simultaneous change in the parameters, $(m, \omega, A_t) \to -(m, \omega, A_t)$ with k_1 being kept the same. The wave functions ψ_+ and ψ_-, eq. (3.76), are exchanged under this transformation. This means

$$C_{1+}(m, \omega, q, k_1) = C_{2-}(-m, -\omega, -q, k_1) \tag{C.1}$$

and

$$C_{1-}(m, \omega, q, k_1) = C_{2+}(-m, -\omega, -q, k_1) . \tag{C.2}$$

In turn, this means that the two conditions, eq. (3.79) can be stated in terms of the coefficients C_{1+}, C_{2+} that characterize the asymptotic behaviour of just one of the solutions ψ_+, as

$$C_{1+}(m, \omega, q, k_1) = 0 , \quad C_{2+}(-m, -\omega, -q, k_1) = 0 . \tag{C.3}$$

It is now clear that both of these will not be generically satisfied for any k_1.

C.1 More details

It is well known that perturbation theory about an extremal background is often fought with subtleties due to the extremal nature of the horizon. For this reason we would like to be carry out a more careful analysis that justifies our approximation of neglecting the k_1 dependent terms in eq. (3.53) when r ranges from being very close to the horizon to values of order eq. (3.57) where the form of ψ in eq. (3.58) can then be used to extract the leading ω dependence as explained in section 3.4.

We use bra-ket notation below and denote,

$$|\psi> \equiv \begin{pmatrix} y_+ \\ z'_- \end{pmatrix}. \tag{C.4}$$

The unit norm eigenstates of σ_2 with eigenvalue ± 1 will be denotes by $|\pm>$ respectively below.

The equations eq. (3.18), eq. (3.19) are

$$r^{\beta+\gamma}\partial_r|\psi> = -k_1\sigma_1|\psi> + i\sigma_2 r^{\beta-\gamma}\omega|\psi> . \tag{C.5}$$

Neglecting the k_1 dependent term gives the zeroth order solution eq. (3.21),

$$|\psi_0> = e^{-i\omega z}|->. \tag{C.6}$$

Let

$$|\psi_1> = F_1|+> \tag{C.7}$$

be the first order correction induced by the k_1 dependent term we have neglected. We get from eq. (C.5)

$$\partial_z F_1 - i\omega F_1 = -k_1 r^{\gamma-\beta} <+|\sigma_1|-> e^{-i\omega z} \tag{C.8}$$

where z is given in terms of r in eq. (3.22). This gives,

$$\partial_z F_1 - i\omega F_1 = ik_1 r^{\gamma-\beta} e^{-i\omega z} . \tag{C.9}$$

The solution is

$$F_1(z) = e^{i\omega z} i d_2 k_1 \int_{-\infty}^{z} dy\, y^{\frac{\gamma-\beta}{1-2\gamma}} e^{-2i\omega y} . \tag{C.10}$$

The constant of integration is chosen by the fact that the full solution must be purely in-going at the horizon. The coefficient d_2 is determined by γ, β. Now notice that since $\beta + \gamma < 1$ the second integral is convergent. By rescaling variables, $x = \omega y$ we get

$$F_1(z) = e^{i\omega z} i d_2 k_1 \omega^{\frac{1-\gamma-\beta}{2\gamma-1}} \int_{-\infty}^{\omega z} dx\, x^{\frac{\gamma-\beta}{1-2\gamma}} e^{-2ix}. \tag{C.11}$$

We need the correction to be small in the region eq. (3.57) so that eq. (3.58) is a good approximation. For $\beta + \gamma < 1$ the power $\frac{\gamma-\beta}{1-2\gamma} < -1$, so that the integral is convergent at the lower end, $-\infty$, but could diverge at the upper end if $\omega z \to 0$. This tells us that to keep the effects of the k_1 dependent term small we should work in the region where $|\omega z| \ll 1$

but is kept fixed as $\omega \to 0$. In terms of r this becomes the condition that $(r/\omega^{\frac{1}{2\gamma-1}}) \gg 1$ and kept fixed as $\omega \to 0$. In this region the upper limit of the intergal in eq. (C.11) is a fixed number and the integral converges.

It then follows that the correction $F_1(z)$ is small for $\omega \to 0$, compared to the leading term which is order unity, since it is suppressed by $\omega^{\frac{1-\gamma-\beta}{2\gamma-1}}$, which is small, due to $\beta + \gamma < 1$ and also $2\gamma - 1 > 0$ from eq. (2.39).

Thus we see that a more careful analysis, where we have calculated the first corrections, shows that the k_1 dependent terms can indeed be neglected in our analysis of section 3.4.

Before concluding let us make two comments. First, a similar analysis could have been repeated keeping the m_1 dependent terms in the equation of motion and shows that these are even less worrisome that the k_1 dependent ones, as we expect on the basis of our arguments in section 3.2. Second, note that when $\beta + \gamma = 1$ the correction eq. (C.11) is logarithmically divergent at the horizon (as $y \to -\infty$ in eq. (C.10)). This means the effects of the k_1 dependent terms will not be small when $\beta + \gamma = 1$ and we will need to include them in our analysis on par with the ω dependent terms.

D More on the $\beta + \gamma = 1$ case

As mentioned in the section 3.3 in this appendix we discuss following issues.

- The detailed analysis to get the solution as in eq. (3.68), from the eq. (3.66) and (3.67), by series expanding the Hankel solution in eq. (3.66) for small argument.

- The analysis to reach eq. (3.71) and (3.72) for the case $k_1 < 0$.

- The marginal Fermi-liquid that arises for $k_1 = \frac{1}{2}(2\gamma - 1)$.

D.1 Analysis with $k_1 > 0$

Eq. (3.66), for $z \ll 1$, can be power law expanded to get a series expansion of χ_- and using eq. (3.67) χ_+ is,

$$\chi_- = \tilde{z}^{\eta+1}\left(c_1 + O(\tilde{z}^2)\right) + i\left\{\tilde{z}^{\eta+1}\left(d_1 + O(\tilde{z}^2)\right) + \tilde{z}^{-\eta}\left(d_3 + d_4\tilde{z}^2 + O(\tilde{z}^3)\right)\right\} \quad \text{(D.1)}$$
$$\chi_+ = -\tilde{z}^{\eta}\left(c_1' + O(\tilde{z}^2)\right) - i\left\{\tilde{z}^{\eta}\left(d_1' + O(\tilde{z}^2)\right) + \tilde{z}^{-\eta-1}\left(d_4'\tilde{z}^2 + O(\tilde{z}^3)\right)\right\} \quad \text{(D.2)}$$

where $c_1, d_1, d_3, d_4, c_1', d_1', d_4'$ are all constants depending on η. For small $\tilde{z}$, it is evident that χ_- dominates over χ_+, (i.e. $i\tilde{z}^{-\eta}d_3$ term from χ_-). Further calculations are divided into two cases depending on η,

- $0 < \eta < \frac{1}{2}$.
  In subleading order, d_1 terms dominate over d_4 term in χ_-. So we get

$$\chi_- = i\tilde{z}^{-\eta}d_3 + \tilde{z}^{\eta+1}(c_1 + id_1) \quad \text{(D.3)}$$
$$\chi_+ = -\tilde{z}^{\eta}(c_1' + id_1'). \quad \text{(D.4)}$$

Using eq. (3.60) and using the fact that $\tilde{z}^\eta \gg \tilde{z}^{\eta+1}$, we get the original wave functions y_+, z'_- as,

$$y_+ = i\tilde{z}^{-\eta}\frac{d_3}{2} - \tilde{z}^\eta\frac{(c'_1 + id'_1)}{2} \tag{D.5}$$

$$z'_- = -i\tilde{z}^{-\eta}\frac{d_3}{2} - \tilde{z}^\eta\frac{(c'_1 + id'_1)}{2}. \tag{D.6}$$

Using eq. (3.61) we can extract the ω dependence from $\tilde{z}$ in the above eq, and up to an overall ω dependent factor, which is not important, the complete wave function in terms of radial variable r can be written as,

$$\psi = \begin{pmatrix} y_+ \\ z'_- \end{pmatrix} = \begin{pmatrix} 1 \\ -1 \end{pmatrix} r^{k_1} + de^{i\phi}\omega^{2\eta}\begin{pmatrix} 1 \\ 1 \end{pmatrix} r^{-k_1}, \tag{D.7}$$

where d is real number dependent on k_1. This is the same as eq. (3.68).

- $\eta > \frac{1}{2}$.

  In the subleading order d_4 term dominates over d_1 terms in χ_-. So we get

$$\chi_- = i\tilde{z}^{-\eta}d_3 + i\tilde{z}^{-\eta+2}d_4 + c_1\tilde{z}^{\eta+1} \tag{D.8}$$

$$\chi_+ = -i\tilde{z}^{-\eta+1}d'_4 - \tilde{z}^\eta c'_1. \tag{D.9}$$

Using eq. (3.60) to go to variables y_+ and z'_-, and upon using the fact that $\tilde{z}^\eta \gg \tilde{z}^{\eta+1}$ and $\tilde{z}^{-\eta+1} \gg \tilde{z}^{-\eta+2}$ we get[37]

$$y_+ = i\tilde{z}^{-\eta}\frac{d_3}{2} - \tilde{z}^\eta\frac{c'_1}{2} \tag{D.10}$$

$$z'_- = -i\tilde{z}^{-\eta}\frac{d_3}{2} - \tilde{z}^\eta\frac{c'_1}{2}. \tag{D.11}$$

Again using eq. (3.60), eq. (3.61), and up to some overall normalization the solution as,

$$\psi = \begin{pmatrix} y_+ \\ z'_- \end{pmatrix} = \begin{pmatrix} 1 \\ -1 \end{pmatrix} r^{k_1} + id'\omega^{2\eta}\begin{pmatrix} 1 \\ 1 \end{pmatrix} r^{-k_1}, \tag{D.12}$$

where d' is a real number dependent on k_1. This is same as eq. (3.69).

D.2 Analysis with $k_1 < 0$

When $k_1 < 0$, the differential equations instead of eq. (3.63) and (3.64) will be now given by

$$(\tilde{z}\partial_z + \eta)\chi_+ = \tilde{z}\chi_- \tag{D.13}$$

$$(\tilde{z}\partial_z - \eta)\chi_- = -\tilde{z}\chi_+. \tag{D.14}$$

---

[37]We drop the terms proportional to d'_4 and d_4 because they are purely imaginary and make a contribution suppressed by powers of ω and ω^2 respectively compared to the leading terms proportional to d_3 which is also purely imaginary. Note that on the other hand, a term proportional to c'_1 are purely real, so we keep this term.

Solutions to the above equations can be easily got by observing the following: χ_+, χ_- now satisfy the same differential equation as $\chi_-, -\chi_+$ satisfied in eq. (3.63) and (3.64). Using this fact and the explicit solution from eq. (3.66) we can write the solution as,

$$\chi_+ = \sqrt{\tilde{z}} H^{(1)}_{\frac{1}{2}+\eta}(\tilde{z}) \tag{D.15}$$

$$\chi_- = \tilde{z}^{-\eta} \partial_{\tilde{z}}(\tilde{z}^{\eta} \chi_+). \tag{D.16}$$

A similar analysis as before goes through with now χ_+ being the dominating solution. Again the analysis is divided into cases,

- $0 < \eta < \frac{1}{2}$.

$$y_+ = i\tilde{z}^{-\eta}\frac{d_3}{2} + \tilde{z}^{\eta}\frac{(c_1' + id_1')}{2} \tag{D.17}$$

$$z_-' = i\tilde{z}^{-\eta}\frac{d_3}{2} - \tilde{z}^{\eta}\frac{(c_1' + id_1')}{2} \tag{D.18}$$

which gives the wavefunction in the radial variable r given in eq. (3.61) as,

$$\psi = \begin{pmatrix} y_+ \\ z_-' \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \end{pmatrix} r^{|k_1|} + de^{i\phi}\omega^{2\eta} \begin{pmatrix} 1 \\ -1 \end{pmatrix} r^{-|k_1|} \tag{D.19}$$

where d is k dependent real number. This is the same as eq. (3.71).

- $\eta > \frac{1}{2}$.

$$y_+ = i\tilde{z}^{-\eta}\frac{d_3}{2} + \tilde{z}^{\eta}\frac{c_1'}{2} \tag{D.20}$$

$$z_-' = i\tilde{z}^{-\eta}\frac{d_3}{2} - \tilde{z}^{\eta}\frac{c_1'}{2} \tag{D.21}$$

which gives the wavefunction in the radial variable r given in eq. (3.61) as,

$$\psi = \begin{pmatrix} y_+ \\ z_-' \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \end{pmatrix} r^{|k_1|} + id'\omega^{2\eta} \begin{pmatrix} 1 \\ -1 \end{pmatrix} r^{-|k_1|} \tag{D.22}$$

where d' is real number dependent on k_1. Therefore to leading order we get eq. (3.72).

D.3 Marginal Fermi liquid for $k_1 = \frac{1}{2}(2\gamma - 1)$

For the specific value of $k_1 = \frac{1}{2}(2\gamma - 1)$, i.e., $\eta = \frac{1}{2}$, something interesting happens. We rework the above calculation with $\eta = \frac{1}{2}$ now, then eq. (3.66) and (3.67) become,

$$\chi_- = \sqrt{\tilde{z}} H^{(1)}_1(\tilde{z}) \tag{D.23}$$

$$\chi_+ = -\tilde{z}^{\frac{-1}{2}} \partial_{\tilde{z}}(\sqrt{\tilde{z}} \chi_-). \tag{D.24}$$

Expansion of Hankel function with index 1 for small $\tilde{z}$ will have a log term in the imaginary part in subleading order. More explicitly,

$$\chi_- = \frac{\tilde{z}^{\frac{3}{2}}}{2}(1 + O(\tilde{z}^2)) + i\left\{\frac{c_1}{\sqrt{\tilde{z}}} + c_2\tilde{z}^{\frac{3}{2}}\log\tilde{z} + c_3\tilde{z}^{\frac{3}{2}} + O(\tilde{z}^2)\right\} \tag{D.25}$$

$$\chi_+ = -\sqrt{\tilde{z}} + i\sqrt{\tilde{z}}\left[c_2'\log\tilde{z} + c_3'\right] \tag{D.26}$$

$c_1, c_2, c_3, c_2', c_3'$ are constants depending on k_1. Since $\tilde{z} \ll 1$, c_1 term dominates over c_2, c_3 terms in χ_-, and c_2' term dominates over c_3' term in χ_+. Note that χ_- has the most dominant term $\frac{1}{\sqrt{\tilde{z}}}$. Now using eq. (3.60) we get y_+ and z_-' as,

$$y_+ = i\left[\frac{c_1}{\sqrt{\tilde{z}}} + c_2'\sqrt{\tilde{z}}\log\tilde{z}\right] - \sqrt{\tilde{z}} \tag{D.27}$$

$$z_-' = -i\left[\frac{c_1}{\sqrt{\tilde{z}}} - c_2'\sqrt{\tilde{z}}\log\tilde{z}\right] - \sqrt{\tilde{z}} \tag{D.28}$$

where we have used $\sqrt{\tilde{z}} \gg \tilde{z}^{\frac{3}{2}}$. In terms of radial variable r, given in eq. (3.61), and upto overall ω dependent factor, we get,

$$\psi = \begin{pmatrix} y_+ \\ z_-' \end{pmatrix} = \begin{pmatrix} 1 \\ -1 \end{pmatrix} r^{-\frac{2\gamma-1}{2}} + g_1\omega\log\omega \begin{pmatrix} 1 \\ 1 \end{pmatrix} r^{\frac{2\gamma-1}{2}} + id'\omega \begin{pmatrix} 1 \\ 1 \end{pmatrix} r^{\frac{2\gamma-1}{2}}. \tag{D.29}$$

where g_1, d' are real numbers dependent on k_1. Using this wavefunction one gets the Green's function as written down in eq. (3.74).

E Scalar two point function

In this appendix we study a bulk charged massive scalar (denoted by Φ, so that it is not confused with the dilaton) and calculate the two-point function for the corresponding operator in the boundary theory.

The action for the charged scalar is

$$S = -\int d^4x\sqrt{-g}\left((D_\mu\Phi)^2 + m^2\Phi^2\right), \tag{E.1}$$

where $D_\mu\Phi = (\partial_\mu - iqA_\mu)\Phi$.

The equation of motion for the scalar field $\Phi = \Phi(r)e^{i\omega t + i\vec{k}.\vec{x}}$ is

$$\frac{1}{\sqrt{g}}\partial_r(\sqrt{g}g^{rr}\partial_r\phi) - (g^{ii}(k^2 - u^2) + m^2)\Phi = 0 \tag{E.2}$$

where u is as given in eq. (3.13). In extracting the correlator in the field theory it is convenient to assume that there is a gravitational background which extends to AdS_4, with radius L, on the boundary and then use the AdS/CFT dictionary to calculate the boundary correlator. Asymptotically towards the boundary, the scalar field will behave as

$$\Phi = C_1 r^\Delta + C_2 r^{-\Delta} \tag{E.3}$$

where Δ is the positive root of the equation $\Delta(\Delta+3) = m^2L^2$. Then the two-point function on the boundary[38] for operator dual to Φ is,

$$G_R = \frac{C_2}{C_1}. \tag{E.4}$$

---

[38]Here we assume the standard quantization for this field.

To obtain the retarded Green's function, we impose ingoing boundary conditions at the horizon. The near-horizon background solution is given by eq. (2.22), (2.23). Setting C_a to unity by rescaling $\vec{k}, m, q$, as for the fermionic case gives,

$$\frac{1}{r^{2\beta}}\partial_r\left(r^{2\beta+2\gamma}\partial_r\Phi\right) + \frac{(\omega+qA_t)^2}{r^{2\gamma}}\Phi - \frac{k^2}{r^{2\beta}}\Phi - m^2\Phi = 0. \tag{E.5}$$

In the near horizon region, the mass term is subdominant, since $r \ll 1$, and also the A_t term can be neglected compared to the ω dependent for the same reason as in the fermionic case: the frequency dependence at small ω can be extracted before the A_t term becomes important. This gives,

$$\frac{1}{r^{2\beta}}\partial_r\left(r^{2\beta+2\gamma}\partial_r\Phi\right) + \frac{\omega^2}{r^{2\gamma}}\Phi - \frac{k^2}{r^{2\beta}}\Phi = 0. \tag{E.6}$$

Just as in the fermionic case it is convenient to divide the analysis into three cases.

E.1 $\beta + \gamma > 1$

Here the equation can be analyzed in the WKB approximation. The analysis is similar to section 3.1 of the fermionic case and we will skip some details. It is easy to see that the WKB approximation is self-consistently valid. Changing to the variable ζ, eq. (3.25) gives that Φ satisfies the same equation as y_+, eq. (3.30). The resulting solution in the region eq. (3.32) is

$$\Phi = \frac{A}{\sqrt{\hat{k}}}\left[f_+ + \frac{i}{2}e^{-2I}f_-\right]. \tag{E.7}$$

We see that f_- has a coefficient which is exponentially suppressed. The factor I in the exponential suppression is

$$I = c_1\left(\frac{|k|^{2\gamma-1}}{\omega^{(\beta+\gamma-1)}}\right)^{\frac{1}{\gamma-\beta}} \tag{E.8}$$

where c_1 is given in eq. (3.40).

Now suppose the coefficients C_1, C_2, eq. (E.3), that f_+ gives rise to are C_{1+}, C_{2+}, and similarly for f_-. And suppose an expansion of these coefficients in a power series in ω has leading order terms denoted by $C_{1\pm}^{(0)}, C_{2\pm}^{(0)}$, the first corrections by $C_{1\pm}^{(1)}, C_{2\pm}^{(1)}$ etc. Then the two-point function is [7]

$$G_R = \frac{C_{2+}^{(0)} + \omega C_{2+}^{(1)}\omega + O(\omega^2) + \frac{i}{2}e^{-2I}[C_{2-}^{(0)} + C_{2-}^{(1)}\omega + O(\omega^2)]}{C_{1+}^{(0)} + C_{1+}^{(1)}\omega + O(\omega^2) + \frac{i}{2}e^{-2I}[C_{1-}^{(0)} + C_{1-}^{(1)}\omega + O(\omega^2)]}. \tag{E.9}$$

Physically, the coupling of the scalar to the near-horizon region is highly suppressed, as a result the imaginary part of the Green's function, which arises because the scalar can fall into the black hole, is also exponentially small.

E.2 $\beta + \gamma < 1$

In this case the leading small frequency dependence can be obtained by studying the region, $1 \gg (\frac{\omega}{k})^{\frac{1}{\gamma-\beta}} \gg r$, thus the k_1 dependent term in eq. (E.6) can be dropped, giving

$$r^{-2\beta}\partial_r \left(r^{2\beta+2\gamma}\partial_r\Phi\right) + \frac{\omega^2}{r^{2\gamma}}\Phi = 0. \tag{E.10}$$

Now define

$$z = \frac{\omega}{2\gamma-1} \frac{1}{r^{2\gamma-1}}. \tag{E.11}$$

Also define

$$\eta = \frac{2\beta}{2\gamma-1}. \tag{E.12}$$

Then in terms of z the differential equation eq. (E.10) is

$$z^\eta \partial_z \left(z^{-\eta}\partial_z\Phi\right) + \Phi = 0 \tag{E.13}$$

whose solution is

$$\Phi = z^{\frac{1+\eta}{2}} H^{(1)}_{\frac{1+\eta}{2}}(z). \tag{E.14}$$

For $\beta + \gamma < 1$ we can be in the region where $z \ll 1$ consistent with the requirement $(\frac{\omega}{k})^{\frac{1}{\gamma-\beta}} \gg r$ needed to drop the k_1 dependent term in eq. (E.6), since, for $\omega \to 0$, $(\frac{\omega}{k})^{\frac{1}{\gamma-\beta}} \gg r \gg \omega^{\frac{1}{2\gamma-1}}$. In this region, the argument of the Hankel function is small and we get,

$$\Phi = d_1 + i d_2 \left(\frac{\omega}{r^{2\gamma-1}}\right)^{1+\eta}, \tag{E.15}$$

where d_1, d_2 are real and we have used eq. (E.11). In fact a constant and $1/r^{2\gamma-1+2\beta} = 1/r^{(2\gamma-1)(1+\eta)}$ are the two independent solutions to eq. (E.10) in this region where the ω dependent term can be neglected. Denoting the constant solution as ϕ_+ and the real solution going like $1/r^{2\gamma-1+2\beta}$ as ϕ_- and taking the coefficients $C_{1\pm}, C_{2\pm}$ to be defined as in the previous case we get

$$G = \frac{C_{2+} + i\, C_{2-}\, \omega^{1+\eta}}{C_{1+} + i\, C_{1-}\, \omega^{1+\eta}}. \tag{E.16}$$

The coefficients $C_{2\pm}, C_{1\pm}$ in turn can be power series expanded in ω as in the previous subsection.

We see that in this case the imaginary part of G is only power-law suppressed in ω with a power, η, eq. (E.12), which is independent of the momentum k and the charge and mass of the scalar.

E.3 $\beta + \gamma = 1$

In this case we define

$$\Phi = \frac{\xi}{\sqrt{r}}, \tag{E.17}$$

then in terms of z, eq. (E.11), eq. (E.6) becomes,

$$z\partial_z(z\partial_z\xi) + (z^2 - \nu^2)\xi = 0 \tag{E.18}$$

where

$$\nu^2 = \frac{k^2 + \frac{1}{4}}{(2\gamma - 1)^2}. \tag{E.19}$$

eq. (E.18) is a Bessel equation whose solution with ingoing boundary conditions is

$$\xi = H_\nu^{(1)}(z). \tag{E.20}$$

When $z \ll 1$, the Hankel function can be power series expanded to get, upto an overall power of ω,

$$\Phi = \frac{1}{\sqrt{r}} \left[d_1 r^{\nu(2\gamma-1)} + i d_2 \omega^{2\nu} \frac{1}{r^{\nu(2\gamma-1)}} \right]. \tag{E.21}$$

Denoting $\phi_\pm$ as the two independent real solutions to the scalar equation in this region which appear in the first and second terms on the r.h.s. respectively of eq. (E.21) and defining $C_{1\pm}, C_{2\pm}$ as the coefficients of the non-normalisable and normalisable terms these give rise to, as above, we then get the boundary two-point function to be,

$$G = \frac{C_{2+} + i C_{2-}\omega^{2\nu}}{C_{1+} + i C_{1-}\omega^{2\nu}}. \tag{E.22}$$

Note that in this case the imaginary part is again power-law suppressed but this time the power, ν, eq. (E.19) is dependent on k^2 and γ while being independent of the charge and mass of the scalar.

F   Extremal branes: from near-horizon to boundary of AdS

In section 2 we investigated a system of dilaton gravity described by the action eq. (2.1). Since we were interested in the behaviour when the dilaton had evolved sufficiently far along a run-away direction we took $f(\phi)$ and $V(\phi)$ to be of the form, eq. (2.2), eq. (2.3). The resulting solution was then of the form eq. (2.13). In this appendix we will show that such a solution can arise as the near-horizon limit starting from an asymptotic AdS_4 geometry perturbed by a varying dilaton. For this purpose we will continue to take $f(\phi)$ to be of the form in eq. (2.2), but instead of eq. (2.3) now take the potential to be

$$V(\phi) = 2V_0 \cosh(2\delta\phi) \tag{F.1}$$

with $V_0 < 0$. This potential has the property that along the run-away direction where, $\phi \to \infty$, $V(\phi) \to V_0 e^{2\delta\phi}$ and therefore agrees with eq. (2.3). As a result the solution eq. (2.13) continues to be a good approximate solution for this potential as well.

In addition, the potential eq. (F.1) also has a maximum at $\phi = 0$, with $V(\phi = 0) = 2V_0 < 0$. This means that the system has another solution where $\phi = 0$ and the metric is AdS_4 with a radius

$$R^2 = -\frac{3}{V_0}. \tag{F.2}$$

Working in a coordinate system of the form eq. (2.6), we will construct a numerical solution which asymptotes between this AdS_4 solution and a near-horizon geometry given by eq. (2.13).

Note that expanding about $\phi = 0$ the potential eq. (F.1) results in a mass for the dilaton,

$$m^2 = -2\delta^2 |V_0|. \tag{F.3}$$

In order this to lie above the BF bound, $m_{BF}^2 = -\frac{9}{4R^2}$, δ must meet the condition

$$\delta^2 < \frac{3}{8}. \tag{F.4}$$

Asymptotically, as $r \to \infty$ and one goes towards the boundary of AdS_4, the dilaton goes like

$$\phi \to r^{\Delta_\pm}, \quad \Delta_\pm = \frac{-3 \pm \sqrt{9 + 4m^2}}{2} \tag{F.5}$$

Since $m^2 < 0$, in both cases the dilaton will fall-off. This corresponds to the fact that with $m^2 < 0$ the dilaton corresponds to a relevant operator in the CFT dual to the asymptotic AdS_4 space-time. In the solution we obtain numerically, in general, the dilaton will go like a linear combination of both solutions,

$$\phi = c_1 r^{\Delta_+} + c_2 e^{\Delta_-} \tag{F.6}$$

Accordingly, in the dual field theory the Lagrangian will be deformed by turning on the relevant operator dual to the dilaton.

In the subsequent discussion it will be convenient to choose units such that $|V_0| = 1$.

F.1 Identifying the perturbation

It is actually convenient to start in the near-horizon region and then integrate outwards, towards the boundary, to construct the full solution.

To start, we first identify a perturbation in the near-horizon region which grows as one goes towards the UV (larger values of r). For this purpose, we will approximate the potential as $V = -e^{2\delta\phi}$ and ignore the correction going like $e^{-2\delta\phi}$ to it, this will lead to a condition on the parameters (α, δ) which we will specify shortly.

Including a perturbation in the metric gives,

$$a(r) = C_a r^\gamma (1 + \epsilon \, d_1 \, r^{\nu_1}); \quad b(r) = r^\beta (1 + \epsilon \, d_2 \, r^{\nu_2}) \tag{F.7}$$

The resulting form of the perturbation of ϕ is determined from the ansatz for b by the equation of motion (2.10):

$$\phi(r) = k \log r + \epsilon \, d_3 \, r^{\nu_2} \tag{F.8}$$

with $d_3 = \frac{4(\nu_2 - 1) + (\alpha + \delta)^2 (1 + \nu_2)}{4(\alpha + \delta)} d_2$. We now proceed to find a solution with $\nu_1 = \nu_2$.[39]

Solving eq.(2.9) and eq.(2.11) to leading order in r, determine ν_1 and d_2 in terms of d_1:

$$\nu_1 = -\frac{3}{2} + \frac{4 + 2\delta(\alpha + \delta)}{4 + (\alpha + \delta)^2}$$
$$+ \frac{\sqrt{(4 + (3\alpha - \delta)(\alpha + \delta)) [36 - (\alpha + \delta)(17\delta - 19\alpha + 8\alpha^2\delta + 8\alpha\delta^2)]}}{2(4 + (\alpha + \delta)^2)^2} \tag{F.9}$$

[39]Other choices might give solutions but we have not studied them.

Figure 3. Region in α, δ plane satisfying $\nu_1 < -4\delta k$.

and

$$d_2 = \frac{-2(\alpha + \delta)^2}{4(\nu_1 - 1) + (\alpha + \delta)(\alpha(\nu_1 - 1) + \delta(3 + \nu_1))} d_1. \qquad \text{(F.10)}$$

Note that d_1 is left undetermined and is a free parameter that characterises the resulting solution. It is also worth noting that the perturbation we have identified satisfies the constraint, eq. (2.12).

In our analysis above to determine the perturbation we approximated the potential $V = -2\cosh(2\delta\phi) \simeq -e^{2\delta\phi}$, while keeping the leading corrections due to the perturbation, eq. (F.7), eq. (F.8). This is justified, for small r if,

$$\nu_1 < -4\delta k. \qquad \text{(F.11)}$$

Figure 3 shows the region in the (α, δ) plane which is allowed by this constraint. In the numerical analysis we will choose values for (α, δ) which lie in this region, and which also meet the condition eq. (F.4).

F.2 Numerical integration

Staring with the perturbed solution in the near-horizon region the equations can be now be numerically integrated to obtain the solution for larger values of r. For this purpose the full potential eq. (F.1) is used.

Figure 4 and figure 5 show the resulting solution for $\alpha = 1$, $\delta = 0.6$, these values satisfy the conditions, eq. (F.4), eq. (F.11). The strength of the perturbation was chosen to be $d_1 = 0.01$.

Figure 4 and figure 5 clearly show that $a(r) \propto r$ and $b(r) \propto r$ for large r, so the solution is asymptotically AdS_4 (A coordinate transformation can be used to set the constant of proportionality to 1 as in the standard AdS_4 space). The dilaton approaches 0, the extrema
Figure 4. Numerical solution interpolating between the near horizon solution and AdS_4 for $\alpha = 1$, $\delta = 0.6$ and $d_1 = 0.01$. The second plot shows that $a'(r)$ and $b'(r)$ approach 1. Red lines denote a, Blue lines denote b.

Figure 5. Numerical solution for ϕ, for $\alpha = 1$, $\delta = 0.6$.

of the potential $\cosh(2\delta\phi)$. Thus the solution interpolates between AdS_4 and solution discussed in section 2 in the near-horizon region.

Qualitatively similar results are obtained[40] if the parameters α, δ and d_1 are varied within a range.[41] The solution continues to asymptote to AdS_4 and the dilaton asymptotes to $\phi = 0$ which is the extremum of V. In particular, $\alpha = 1, \delta = 0.6$, for which the results are presented in figure 4 and figure 5, corresponds to $\beta + \gamma > 1$. The range of values for which we have found qualitatively similar behaviour includes also cases where $\beta + \gamma \leq 1$.

One final comment about parameters. For a given α and δ there should be a two-parameter family of solutions corresponding to the chemical potential μ and the coupling constant of the relevant operator dual to the dilaton in the boundary theory. Our solution above has one parameter d_1 which is the strength of the perturbation in the IR. Another parameter, which can be thought of as changing the overall energy scale in the boundary theory, corresponds to a coordinate rescaling in the bulk, $(r, x^\mu) \to (\lambda r, x^\mu/\lambda)$. Under this coordinate transformation the charge Q, eq. (2.7), transforms as $Q_e \to \lambda^2 Q_e$.

---

[40]The value, $\delta = 0.6$, is such that both quantisations for the dilaton are possible. Our conclusion that qualitatively similar results are obtained continues to also hold when $|\delta|$ is chosen to be somewhat smaller so that only the standard quantisation is allowed.

[41]We work in the region where eq. (F.11) and eq. (F.4) are met.
